As practiced on the Comstock, and generally on the coast, the shaft timbering consists of framed sets or cribs of square timber, placed horizontally, four feet apart, and separated by uprights or posts introduced between them. Each horizontal set of timbers, therefore, marks about five feet in depth. Cross-timbers for the partitions between the compartments form a part of every set. The whole is covered on the outside by a lagging of three-inch plank placed vertically. This method of timbering is illustrated by several drawings on this page. Fig. 1 represents the plan of the shaft, or of one horizontal set of timbers; *S. S.* are the longitudinal or sill timbers; *T. T.*, the transverse end timbers; *P.*, partition timbers; *R.*, guide rods, between which the cage moves; *G.*, gains cut in the sill timbers to receive the ends of the posts. The sheathing or lagging is seen inclosing the whole frame.

Fig. 2 is a transverse section through the par-

Fig. 4.—Longitudinal Section of Shaft.

Fig. 5.—End View of Shaft.

S. Land Office, are worthy of preservation in this condensed form, and miners will do well to cut the article out and put it away for reference.

MANGANESE AS FLUX.—The Tombstone company's smelter at Charleston has again shut down. It is said that it will start up again about the 1st of March. We fear that it will have to be admitted that manganese as a flux, other than in limited quantities, will have to be pronounced a failure. There seems to be no substitute for lead in smelting dry ores, and the Tombstone company's tailings are too poor in lead to make the smelting a success, except more lead can be got to work with them.—*Tombstone Republican*.

THE original Benson smelter has been torn down, and a Pacific coast furnace has been put up in its place. This shows that there is no money in putting up a square barn of a concern, where cold corners are always causing the furnace to freeze up.—*Tombstone Republican*.

THE Bodie Miner says that Sweetwater is supposed by many to be a better camp to bet on for permanency than Cory.

THE engineer, who hoisted to the surface the last lot of men that came out of the Yellow Jacket disaster on the Comstock, was Frank Kellogg, who died recently in Mason valley.

THE Deadwood-Terra mine passed the dividend this month for the first time since the consolidation of these claims.

tion *P.* of Fig. 1, between the pumping compartment and the adjoining hoisting compartment, looking toward the latter. In this figure, *G.*, *G.* are the posts; *S.*, the sill timbers; *P.*, the partition timbers, the ends of which are framed with short tenons that are received in gains cut in the sill timbers and the ends of the posts; *r.*, guide rod; *l.*, lagging or sheathing.

Fig. 3 is an end view of the frame shown in Fig. 1. The single piece, *T.* forms the ends, while the double pieces, *P.* forming the partitions, are seen beyond. The other letters denote the same parts as in Fig. 2.

The outer timbers of each set, that is, the two sides and ends of the main frame, are 14 inches square. The posts, 10 in number, four at the corners and two at each end of the three partitions, are of the same size. The dividing timbers forming the partitions are 12 inches square. These partitions, as may be seen in the drawing, are not close, no planking or lining being used on them, but two pieces of timber are employed, one above the other, at each set, leaving open spaces of about three feet between the sets.

The ground through which these shafts pass being generally too unsettled to allow of sinking to any considerable depth without support, the work of timbering is necessarily done from above downward, as the sinking progresses.

The method of putting these timbers in place is about as follows:

When sufficient ground has been excavated below the last set of timbers, for conveniently putting in another lower set, the long horizontal timbers, or sill-pieces, forming the sides of the set already framed for receiving the ends, and having gains cut for the posts and cross-pieces, or ties, are lowered down and put approximately in place; being hung by chains to the last set already fixed above. The sill pieces are usually in two parts, each about 13 feet long, batted together at the middle, without splice or framing. The ends, cross-pieces and posts are then fitted as nearly as possible into their proper places. This being done, several long, round iron bolts, each made in two parts with a tightening screw in the middle, are passed through the new set and the one, or sometimes two or more, above. Everything being approximately in its place, the new set is adjusted exactly to its proper position, by means of the tightening screws on the bolts by which it now hangs to the set above. The lagging is then put in behind the timbers, and between the plank and the ground are inserted pieces of spiling and wedge-timber, which are driven into place or forced in by jackscrews as firmly as possible. Once fixed in this manner, everything is held by lateral pressure; the bolts by which the set was at first suspended are allowed to remain for a time and then withdrawn, for use in placing succeeding sets.

The shafts on the Comstock timbered in this manner generally stand very well and are maintained in good condition. When movements of ground force any part of the work out of line, the disturbed sets may be taken out and replaced by new, or readjusted without difficulty; and, unless the ground is very bad, with a tendency to move in large masses, the perpendicular line of the shaft may be well preserved.

When it becomes necessary to retimber a shaft or any considerable part of it, the work is usually carried on in one compartment or one half of the shaft, while the remaining compartments are kept for use in the ordinary operations of the mine.

Nearly all the deep shafts of the Comstock mines have required more or less retimbering. This has been especially the case in the deeper portions, near the vein, where the ground passed through is sometimes very heavy, consisting of massive clay which exerts a tremendous pressure on the timbers. To withstand this latter it is sometimes necessary to resort to methods still more substantial than that just described. In uncommonly heavy ground a shaft is timbered with double sets, and outer set inclosing the ordinary single set, giving additional strength to the frame. In the bad ground very large expense is involved for the proper maintenance of the work. Some of the retimbering is done with 14-inch timbers, placed in sets not four feet apart, as just described, but close together, making a solid casing 14 inches thick. In some shafts the sill pieces are made in two parts of unequal length, one long and one short piece, and in each succeeding set these pieces are so placed as to break joints, the joint running opposite one or the other of the timber partitions between the compartments. The corners of the frame are joined together simply with a nitred joint (as shown in Fig. 1); and the end pieces are placed transversely between them, in such a manner that the end of each transverse piece bears with half its thickness against two adjacent sill pieces.

Figs. 4 and 5 illustrate this method of construction. Fig. 4 is a longitudinal section of a portion of the shaft, showing one end and two partitions. The sill timbers are laid close together, one upon another; the end timbers are placed in a similar manner, but breaking joints with the sill timbers, as shown in Fig. 5, which is an end view of the shaft. The partition timbers are placed like the end timbers, one upon another, but their ends are not let into the sill timbers by any gain or mortice; the sills are dressed smoothly to receive the ends of the partition timbers, which are then put in place without any framing.

The cost of making these shafts is not very readily ascertained, because, in most cases, the expense of making the shaft is involved in the accounts with other general expenses of the mine, so that an accurate and minute analysis is almost impossible. One shaft, cited by Mr. Hague, at a depth of 1,129 feet, had cost \$180 per foot. Deeper shafts cost more in proportion.

Metallurgy and Ores.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'S SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

BUNTLINE FOR REEFING SAILS.—Ira A. Storer, S. F. Dated Feb. 13, 1883. No. 272,171. This invention relates to certain improvements in sails and their running gear; and it consists in the addition of certain lines which the inventor calls "purchase buntlines" whereby a portion of the sail may be hauled up to render the clewing up for the remainder an easier matter; and in certain strengthening ropes upon the forward part of the sail. When a sail is very large, as in a top-gallant sail, for instance, great difficulty is found in clewing them up. This has led to the placing on large vessels of two yards—the upper and lower top-gallant yard—and of bending on each a top-gallant-sail-upper and lower. These sails are each worked by its own set of running gear and the advantage obtained is in dividing a large sail into two smaller ones, each of which is comparatively easy to be handled. But the obvious objections to the plan are, that a sail is more effective as a single sail than when the same amount of canvas is made into two sails; that there is too much weight aloft; that it requires too much gear; and that two yards and gearing are more expensive than one. The object of Mr. Storer's invention is to retain the single large sail, and, by a proper arrangement of additional running gear, avoid the difficulty of clewing up, and also by a proper strengthening of the sail to economize in the character of the canvas and still have the sail as strong as before.

ROTARY HARROW.—James R. Bane, of Gilroy, California. No. 272,112. Dated Feb. 13, 1883. This invention relates to certain new and useful improvements in rotary harrows, and more especially to that class in which concentric rings are made to revolve in opposite directions. The improvements consist in the means by which the opposite rotation is effected, and in a means for supporting the harrow rings to limit the depth to which the teeth may penetrate, and to prevent friction. The object of this invention is to provide an effective and simple harrow.

GRAIN SEPARATOR.—Martin Wilcox, of Paskenta, California. No. 272,178. Dated Feb. 13, 1883. This invention relates to improved means for separating wheat from barley, oats, and small grains or seeds, after the grain has been cleaned from the straw and chaff.

In countries where malaria is prevalent, or where the climate is subject to sudden changes—should be found in every house Brown's Iron Bitters.

Signal Service Meteorological Report.

ESTHETICISM appears to be dying out in England. The exchange column of the ladies' newspapers have many offers of art embroidery of sunflowers and lilies on sagegreen cloth, and Oscar Wilde's return has evidently excited no enthusiasm.

THE membership of London clubs aggregates nearly 100,000. Their property is worth something over \$25,000,000. There are clubs exclusively for clergymen, and others whose members devote their meetings only to high gambling.

Failing!

That is what a great many people are doing. They don't know just what is the matter, but they have a combination of pains and aches, and each month they grow worse.

The only sure remedy yet found is BROWN'S IRON BITTERS, and this by rapid and thorough assimilation with the blood purifies and enriches it, and rich, strong blood flowing to every part of the system repairs the wasted tissues, drives out disease and gives health and strength.

This is why BROWN'S IRON BITTERS will cure kidney and liver diseases, consumption, rheumatism, neuralgia, dyspepsia, malaria, intermittent fevers, &c.

Mr. Simon Blanchard, a well-known citizen of Hayesville, Meade county, Kentucky, says: "My wife had been sick for a long time, and her constitution was all broken down and she was unable to work. She was advised to use Brown's Iron Bitters, and found it to work like a charm. We would not now be without it for any consideration, as we consider it the best tonic in the world."

BROWN'S IRON BITTERS is not a drink and does not contain whiskey. It is the only preparation of Iron that causes no injurious effects. Get the genuine. Don't be imposed on with imitations.

IRON SLUICE RIFLE.

I have an Iron Rifle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address, ALMARIN B. PAUL, Room 20, Safe Deposit Building, San Francisco. The following speaks for itself: INDIAN SPRING DRIFT MINE, Feb. 24, 1883. Mr. A. B. Paul:—I have tried your Rifles thoroughly, and find them a fine Rifle. They are good with quicksilver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which glide over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them. B. G. McCLAIN, Superintendent Indian Spring Drift Mine.

Successful Patent Solicitors.

As DEWEY & CO. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

O. W. McCREW—Santa Clara county.
 M. P. OWEN—Santa Cruz county.
 J. W. A. WRIGHT—Merced, Tulare and Kern counties.
 JAMES C. HOAG—California.
 B. W. CROWHILL—Los Angeles and San Bernardino counties.
 L. WALKER—Sacramento, San Joaquin and Stanislaus counties.
 N. H. HAPGOOD—Plumas county.
 A. C. KNOX—Santa Clara county.
 M. H. JOERFUS—Eureka, Nev.
 GEORGE McDOWELL—Sonoma and Mendocino counties.

A Cheerful Recommendation.

BENTON, CAL., February 4, 1883.

Messrs. DEWEY & CO., Patent Solicitors:—I am in receipt of my patent, "Improvements in Vehicle Brake," obtained through your Agency, and would say I am much pleased with thorough and graphic description in specifications and drawings, and can cheerfully recommend you to anyone wishing to obtain favors in your line.—Truly yours, G. R. DUVAL.

CHEAP ORE PULVERIZER.—There is for sale in this city, as will be seen by our advertising columns, a second-hand Rutherford Pulverizer, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Cash in Advance.

Our terms are cash in advance for this paper. NEW NAMES will not be entered on our printed list until payment is made. Feb. 1, 1883.

F. G. BECKETT,

Manufacturer of

Repairing Promptly Attended to.

No. 44 FIRST STREET, SAN FRANCISCO, CAL.

"THE \$1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by and Feeding.

The accompanying cut illustrates the recently introduced
Ore Feeder, and also the Spring Attachment, which replaces the
Weight heretofore used, and which are obvious improve-
ments.

It is now fully demonstrated, after careful and long con-
tinued experimentation and practical use, that the plan
upon which a perfect Ore Feeder must be constructed is that
of a carrier, and not that of a shaking table. Uniform and
accurate feeding is not possible upon the latter plan. The
ore must be evenly carried, upon a steadily advancing plane
or table, to the line of discharge, and there simply dropped
jerky or spasmodic contrivances will not answer the purpose
for wet or sticky ores.

The Challenge Ore Feeders are now in Use in
the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Utah County, Utah, the
"Eclipse" Feeders, (conceived by E. Coleman) were intro-
duced, but not carrying a regular supply of ore for the crush-
ing capacity of the stamps, were replaced by the "Challenge"
which are now running and the stamps crushing forty (40)
per cent. more than was done by the "Eclipse".

The "Harshaw" or "Hermosa" Mill, of Patagonia Dis-
trict, Arizona, was also originally fitted with "Eclipse"
Feeders, but after a few weeks' trial they were pronounced
inadequate to the work, discarded, and the "Challenge"
adopted.

The "Silver King" Mill of Arizona, also removed the
"Eclipse" Feeders to give place to the "Challenge".

The "Sola" Mill, of Brown's Valley, Yuba County, Cal.,
was fitted with "Victor" Feeders, manufactured by E. T.
Steen, but proving insufficient, the "Challenge" Feeders were
substituted.

Four of the "Victor" Feeders, manufactured by E. T.
Steen, were also placed in the "Alexander" Mill, at Grants-
ville, Nevada, but after a fair trial were discarded, and Hen-
dy's Feeders fitted, and four others of the same pattern ad-
ded when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

JOSHUA HENDY, Agent,
Machine Works 49 and 51 Fremont Street, San Francisco.
Manufacturer of Quartz, Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRA-
HAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING

BLAKE STEAM PUMP.
More Than 16,000 in Use.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—DR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinchley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street,
Nov. 6, 1882.

GIANT POWDER.

MANUFACTURED UNDER ALFRED NOBEL'S ORIGINAL AND ONLY VALID PATENT FOR NITRO-GLYCERINE POWDERS. All Nitro-Glycerine Compounds, for instance, so-called HERCULES, VULCAN, VIGORIT, NITRO-SAFETY Powder, Etc., are infringements on the Giant Powder Co.'s Patents.

THE GIANT POWDER COMPANY

Call Special Attention to their Improved Grades of Powder.

NO. 1.—The most Powerful Explosive Compound now in use here.

NO. 2.—Surpasses in strength any Powder of its class ever manufactured.

NO. 3.—This grade is a Strong and Reliable Powder, which does excellent work.

JUDSON POWDER

Is now used in all large Hydraulic Claims, and on most Railroads. It breaks much more ground, and obviates reblasting by breaking much fiercer. TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The Giant Powder Company have also purchased from Mr. Nobel, the inventor of Nitro-Glycerine, his latest invention, known under the name of

NOBEL'S EXPLOSIVE GELATINE

This explosive is from 50% to 60% stronger than the strongest Nitro-Glycerine Compound and impervious to water. Even hot water does not diminish its strength. We are now introducing the same.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

VOLUME XLVI
Number 10.

Saving Gold on Snake River.

In reply to the letter sent us by Mr. F. W. Noble, of Detroit, Michigan, asking information as to the best method for saving the gold on Snake river, and published by us two weeks since, we remark, that the writer of that letter is undoubtedly correct in saying the gold on Snake river, though exceedingly fine, is free from oxide or rust. The trouble in saving it does not, therefore, consist so much in its refusing to amalgamate with quicksilver as in the difficulty of bringing these fine particles in contact with that metal, as used in the ordinary way.

The excessive fineness of this dust is due to the fact that the most of it has traveled a long way from its primary source, hundreds of miles above in the Wind River mountains. The country traversed by the Snake after it leaves these mountains is almost everywhere slightly auriferous, the surface soil in many places showing, under careful prospecting, minute particles of gold. As this is an almost rainless region, but little of this surface soil is ever washed into the river, hence the placers along the latter do not probably receive much enrichment from this source.

As Mr. Noble observes, there has been no lack of methods and machines which the inventors have claimed would overcome that difficulty here complained of, as some of them perhaps will do, operating in a slow and limited way. But these Snake river placers, in order to pay, require to be worked on an extensive scale, an end that can be accomplished only through the employment of large apparatus and large quantities of water. A closer saving of gold, if any be made, will have to be effected through improvements applied to the sluice as now used. Toy machines, however well they may work in a miniature way, will never do where so much material has to be handled.

The best results in washing on Snake river have been reached through the employment of Denniston's silver coated amalgamating plates, manufactured at 655 Mission street, in this city; these, wherever properly used, having been found to answer an excellent purpose. In the few cases where these plates had failed to give entire satisfaction, such partial failure was due to improper management on the part of those using them, or to the fact that the plates ordered were too lightly coated to do good work, some miners, in the practice of a false economy making this mistake. Plates costing less than \$3 per square foot should never be used for work of this kind. Anything cheaper is liable to cause disappointment, the effectiveness of the plate from \$3 up to \$5 per square foot being in the ratio of the price.

If parties mining on Snake river will supply themselves with these plates, procuring those of the best quality and properly protect them with screens when laid in their sluices, they can hardly fail of success. This done, they will at least have availed themselves of the best gold saving appliances for that class of mines extant, at least, the best of which we have any knowledge.

There is this further to be said in explanation of the trouble that has so attended placer operations on Snake river; the majority of the miners there have had but little experience at the business, being recent arrivals from the east. Besides lack of skill, these novices are apt to

perform their work in a hurried and careless way. In cleaning off the silver plated sheets of copper, where these are used, this is especially noticable, these novices in removing the amalgam, employing often sharp or pointed implements for that purpose. Through this practice the silver coating is scraped off or the plate otherwise injured. The experienced miner

METHOD OF FORMING JOINTS IN TIMBERS FOR MINES.

knows that the amalgam, when very hard should be softened with quicksilver applied with a soft cloth, after which it can be scraped off readily and without injury to the coating of silver.

Mine Timbering—No. 5.

Such is the excellence of the systems of timbering which have been adopted on the Comstock, that they have come into use in all the

CROSS-SECTION OF GOLD MINE IN NORTH CAROLINA.

other mining regions on this coast and elsewhere in this country. Carpenters who are used to framing these timbers are in demand everywhere. It was only the other day that the boss carpenter of the Ophir mine was induced to go to Mexico to superintend the timber work to be done on a mine there. We have in this series of articles shown several views of the systems of timbering. The engravings presented herewith show the details of the joints of the timbers for the sets in stopes. The engravings are clear enough to be readily understood without much explanation, the method of framing being apparent by the dotted lines. This will be found useful to miners everywhere.

THE MINING AND SCIENTIFIC PRESS is most assuredly the best paper a miner can read. It should receive the support of every miner. Send 10 cents for a sample copy.—*Georgetown Gazette.*

Distribution of Gold.

The following paper "On Some Peculiarities in the Occurrence of Gold in North Carolina" was read at a recent meeting of the American Institute of Mining Engineers, by Prof. W. C. Kerr, State Geologist, Raleigh, N. C. :

"The distribution of gold is obviously much

wider than is commonly supposed. Besides the usual matrices, veins, or associates, such as quartz, pyrite, chalcopryite, etc., I find it occurring in quite a range of common rocks. For example, at the Rhodes mine, in Gaston county, a body of 9 to 12 feet of decomposed, light-gray gneiss was worked together with the strings of quartz, and yielded from \$6 to \$10 to the ton. A mine in Moore county yields its

northward from near the mouth of the Uharie river, including the Russell, Beck, Laughlin, Jones and others, come under the description just given. These slates, shales, or schists, stand almost vertical, and are generally decomposed to a considerable depth, 20, 40 or 50 feet, and are excavated *en masse*, generally with pick and shovel, sometimes through a cross-section of several hundred feet in length, and the whole mass is carried through the stamp mill and rocker.

"The accompanying diagram represents the last-named mine in cross-section. It is simply an open cut in the side of a hill, 50 to 70 feet high, formed by a ravine which has cut across the strike of the formation. The workable strata, between *a* and *a'*, differ imperceptibly from the bounding rocks, and they pass insensibly into each other, and outside strata becoming gradually more heavily bedded, hard, and quartzose. Within the worked area there are lean strata, that are harder and thicker, and more quartzose or chloritic, as at *b*, *b'*, *b''*. At *d* a portion of the strata is charged with a fine-grained pyrite, that sometimes constitutes a large percentage of the rock for two or three feet in thickness. At *c*, *c'*, *c''*, portions of the strata are crusted with ferruginous scales and limonite, resulting from the decomposition of pyritous masses of slate. This mine may be taken as a type of an extensive zone of mines, that extends even beyond the Yadkin and into South Carolina, including the well-known Brewer mine.

"Within a few months past I have found that the gray, much-jointed quartzites and felsites of the Huronian hills, on the eastern side of the great slate belt, carry a workable percentage of gold through masses of great extent. Gold has also been found by Mr. Hanna, of the Charlotte Mint, in a trap dike that is to be seen in that vicinity. From the facts here given, it would seem that gold is so widely diffused that we may expect to find it in any kind of rock."

Eureka Notes.

The following fresh notes from Eureka, Nev., in addition to what we published on our second page, are contributed by our regular correspondent, Mr. M. H. Joseph :

At the Alexandria mine, the Diligence shaft is being cribbed, and a station is being cut out at the 100-foot level, whence a drift will be run westerly into the hill. More or less ore is being extracted from the old workings, and the work of developments will be vigorously pushed along in the lower levels as soon as the station mentioned is made ready for the work.

At the Grant mine, on Prospect mountain, near Ruby Hill, a drift is being driven towards the Grant incline shaft, where there is a large body of low-grade quartz ore in sight. This drift is already in ledge formation, and promises well for valuable developments.

There are four men at work in the Uncle Sam crosscut of the Albion mine, where the indications of ore are said to be improving. The wages of these men are guaranteed by parties who are anxious to discover new ore bodies. Mr. F. J. Reed, superintendent of the Eureka Con., has charge of the work at present, and I believe will continue in charge. He thinks that the chances for making the mine pay by economical management are good. No arrangements have yet been made to pay up the company's indebtedness. A miners' meeting is now being held at the Courthouse.

The ore from the Richmond mine is said to be improving in quality; it carries a large percentage in gold.

A fine vein of rich carbonate ore has been struck in the Members mine on Adam's Hill.

At the Silver Nugget mine on Silverado Mountain some very heavy lead ore of good quality is being extracted. It is said that the Rescue mine will be equipped with a steam hoisting engine in a few weeks, and work will be resumed thereon as soon as it is placed in position.

"The range of noted mines extending 20 miles

CORRESPONDENCE.

Notes from Eureka, Nevada.

[From our Regular Correspondent.]

At the Eureka Con. everything is running smoothly, with little or no change to note. The new machinery is working to a charm.

The Richmond Con. paid a dividend in London, on the 7th inst., of five shillings per share. Exploration work is being carried on with energy in 23 different places in the mine. There is low grade ore in several of the drifts, and some good ore also. The Eureka Tunnel improves daily. While excavating over the engine shaft to make place for the machinery, a vein was discovered from which five sacks of rich lead ore was taken. This will be developed in due course. The 105 level, south drift, has been extended during the week to the Luke chamber, where the ore is striking easterly and gaining strength with its dip. West of this is the Addison chamber, now producing some of the finest quality of ore that has yet been taken out of the mine. It is very heavy, and assays about \$150 per ton, all in silver. It runs in and out among howlders of lime and promises to make into a good sized body at greater depth. As nearly as I can judge this is situated about 60 feet south of the tunnel line and 115 below it in depth.

At the Silver State mine, the east crosscut from the tunnel is in a more favorable formation than I have ever seen it before. The seams are filled with talc of a greenish hue, and black oxides of manganese. The rock has changed from very hard to a medium hard and soft picking. At the Grand mine the tunnel has been driven about 150 feet to the Geraldine shaft, and from that point it has been run in an irregular northeasterly course, following open seams that make around huge limestone boulders. The indications are favorable for striking ore. A new drift will be run towards the foot of the main incline shaft where there is a large body of low grade quartz, intermixed with which are veins of very rich yellow carbonate ore. At the Fair Play mine,

Pinto District,

work has been suspended for the present, on account of the absence of the superintendent, who is also a large owner. This is an excellent property. It has an incline shaft down 140 feet, at the bottom of which is a very promising ledge formation carrying ore of high and low value. In the upper stopes the vein has been much narrower, but the ore has been sufficiently rich to pay expenses and leave a balance to the account of the owners whenever shipments have been made. The Sparrow mine, near the Fair Play, has splendid croppings of fine quality ore, traceable upon the surface for a distance of 300 feet. An incline shaft, sunk upon the fissure to a depth of thirty feet, is in excellent ledge matter, showing heavy galena ore of high grade. These mines are in that portion of Pinto district known as Alhambra hill.

Silverado Mountain,

Which lies to the westward of it, is at present receiving a great deal of attention from local mining men. The Berryman Brothers are here working actively and deriving good profit from their labor. They are now engaged in removing the waste rock that has accumulated in the old chambers of the Diagonal mine, where there has been stripped and broken down, large quantities of quartz that will work at the furnaces \$50 per ton. All through it there is a great deal of very rich ore. They expect to ship 100 tons of this in about two weeks. The prospects in other parts of this mine are excellent. A small seam of ore has been found in the south drift, 50 feet below the tunnel level. This will be followed and opened up shortly, as here is where it is expected that the continuation of the ore chambers above will be found. Some very fine ore is being extracted from the Silver Nugget mine adjoining it. It is rich in fact as it is in appearance. The Western Globe mine loses nothing in value as development work is pushed along. The main shaft is now down 120 feet from the surface, and 60 feet below the tunnel level, from where some very rich ore is now being extracted.

The Berryman Tunnel and Mining Company are proceeding cautiously to work. A small force of men are employed prospecting upon the surface of their claims, with a view to ascertaining the best place to commence driving their tunnel. The result will probably be made known after a meeting that is to be held in about two weeks from date hereof.

Good reports are coming in from the Spring Valley Mines, although they are being worked on a very limited scale. I intend making a trip to that locality as soon as the snow disappears.

M. H. JOSEPH.

THE CANARY BIRD BUSINESS.—It is estimated that there are at least 14,000,000 pet canary birds in the United States, which annually consume 168,000,000 (\$4,000,000) of seed, costing to consumers at least \$14,000,000. There are 22 manufactories of cages, which turned out 1,000,000 cages last year, worth about \$2,000,000.

WASP NESTS DANGEROUS.—It is said that wasp nests sometimes take fire spontaneously, ignition taking place from the chemical action of the wax of the cells upon the paper covering of the nests.

Humboldt County Lumber Interests.

The annual report of the Chamber of Commerce of Eureka, Humboldt county, by John Vance, President, and Fred W. Bell, Secretary, contains much interesting information concerning the progress of industry and enterprise in Humboldt county. It is claimed that there is discernible a greater disposition toward effort and investment in developing the resources of the county at present than ever before in its history. Wealth does not now go out of the county to carry on enterprises, more or less satisfactory, in other fields. On the other hand, the returns from remunerative home investments are aiding in various public improvements which are vital to the future growth of the county. It is indeed a fortunate county which can say this. There is also considerable outside capital coming in continually and finding satisfactory opportunities for profitable enlistment.

The lumber interest of the county is, of course, its leading source of wealth. It is shown that the exports of sawmill products to domestic ports during the last year reached a value of nearly \$2,000,000. The forest is, however, receding, and new enterprise is being required to bring the logs to the saw and the product to the ship. The report says:

The time has gone by when our foremost interest must depend on the primitive method of the past to supply the stock on which our mills are to be kept running. The "snaking" process, with the stag team and the truck and tramway, or the uncertain floods of winter, can neither singly or all together afford the needed facilities of transport from the heart of our forests to tide water. Lines of railroad diverging from the bay and reaching their limit by the cheap and easy grades of our principal valleys to the remoter parts of the county, is a magnificent scheme of internal improvement for us. While it would give to the mill and timber interests guarantees of almost unlimited development, it would in a corresponding degree give a vigorous push to every other form of production. The system of improvements referred to is evolved from enterprises quite distinct in their organization, each of which must rely for maintenance on the advantages of route it may respectively occupy.

Embracing the different lines within the county, we begin, at the north in their order, with the Trinidad Mill Co.'s railroad from the port of Trinidad to Big Lagoon, ten miles in length. Some four miles of this road is completed and in running order, the balance will be completed during this year. Next, the Vance railroad, ten miles in length, crossing Mad river four miles from the mouth, and in the direction it is now penetrating is unsurpassed for the scope and quality of forest treasures it must bring to its support. The extension of the Arcata Transportation Company's railroad gives it a present length of about eight miles, with a proposed terminus some two miles up the south side of the same stream, the whole of which will be completed before the close of the present year. After the Arcata we come to the late enterprise of Flannigan, Brosnan & Co., a short line on the east of the upper bay, and the Carson road of about the same extent; and lastly, on the bay to north of Eureka, the Freshwater railroad of D. R. Jones & Co., seven miles in length and yearly being extended. These are all constructed by private parties, with the most substantial of roadbeds, iron T rails, thoroughly equipped and operated by first class locomotives. Like those just mentioned, the Elk river railroad (projected by an incorporated company) has special reference to the opening up of a vast body of redwood situated on and adjacent to its route. This will terminate at the old site of Bucksport, and be of a length of eight miles. The company has done the preliminary work for grading and construction the ensuing summer. But, perhaps, the most important of all, as affecting the material interests of our people, the transportation of merchandise and farm products, are the two railroads lately projected from the bay by the way of Eel river valley toward the southern and southeastern portions of the county. Both franchises are incorporated and known under the respective names of the Eel River and Eureka R. R. Co. and the Humboldt Bay and Eel River Co. The former extends from Eureka 45 miles, following in part Eel river valley and terminates on the Van Duzen fork. The latter, starting from Southport on the South bay, follows the same valley 25 miles with a present terminus fixed at Eagle prairie. Work on each of these enterprises is actively prosecuted, and in the early spring a large force of laborers will be required with a view to carry them to a speedy completion.

Certainly, with these radiating railroads, owned chiefly by residents, the county will be better provided with means of transportation than most other counties in the State, and all classes of produce can be brought to the seaport, whence cheap water transportation can be had to other markets.

SIXTEEN MILLIONS PER ACRE.—A lot at the corner of Broad street and Exchange Place, N. Y., recently changed hands at the rate of \$15,000,000 per acre. The ground for the Drexel building was purchased at the rate of \$14,000,000 per acre. The most desirable lots on Broadway are selling at the rate of \$2,000,000 per acre. Real estate in New York is "up."

The consumption of tobacco in France during the past five years has averaged 33,000 tons. The revenue amounts to \$50,000,000 a year.

San Bernardino Mines.

The *Calico Print* says: We often hear new comers, after they hastily examined some of the mines of this district make the remark: "Why don't they go on with their work of developing? are they afraid to go down?" In most instances we think this question can be satisfactorily answered. Of course there are some prospectors who have put up monuments on some land, dug a small hole in the ground, and then walk the street imagining that they will soon be millionaires, that some unsophisticated capitalists will come along, seize their immensely rich specimens with avidity, and give them a big check for their "mine." It is unnecessary to say anything further concerning such, but to leave them to the inevitable result of their folly.

There is another class of prospectors who have located claims, prospected them and taken out small quantities of good ore, but are unable to develop them very rapidly on account of a lack of means. This class hold their claims at a higher figure than capitalists are willing to give, and they would prefer to work their claims themselves and make them pay as they go down on them. There are others who have good claims which they are working cautiously, but surely, with as little expense as possible, but have no intention of stopping until they have exhausted their mines. Because they move slowly some persons think they are afraid to go down; but such is not the case.

There is another class that have the means to develop their claims, but when they strike a rich deposit which soon "plays out" they stop operations, and proceed to figure around to get some one to buy them out or take an interest. Such persons are unwilling to take the chances incident to mining or any other business where there is a liability of failure. They act very unwisely, for it is unreasonable for them to expect that any one else will invest in claims that they are afraid to develop. If they sell at all it will be at a very low figure, the purchaser being willing to risk only a small amount in further testing the merits of the claims.

This camp is new and very little has been done towards developing the mines until recently. Operations have commenced in earnest on the King, Burning Moscow, Oriental, Silver Odessa, San Houston, and others, and by the time the Oriental mill is completed there will be many thousands tons of ore ready to be milled. There is a great deal of rich ore in sight and the indications that the mines are rich are unusually good. Old miners declare they have never seen a district that possessed such flattering prospects on the start as this. Even the outlook of Virginia City during the first year was not so bright as can be seen here. This camp is building up on its own merits, and in the near future the quantities of bullion that will be produced will show to the world the richness of our mines.

Assessable Stock.

At the risk of being thought tedious, it seems important that attention should be again called to the importance of a change in the corporation law, which shall allow mining stocks to be assessed. The matter entered somewhat into our late election, and it was then understood that the several candidates were heartily in favor of such a change. The law of Nevada or California upon this subject would be most acceptably applicable to the situation of things in this Territory. Of course, if corporations do not like the assessable plan, they can incorporate in New York or Boston. The interests of miners, investors and business men are involved in this matter. The general interests of this Territory, of farmers who have anything to sell, of freighters and men whose business depends upon the healthy development of our resources, demand that the statutory embargo on mining enterprise, by which that industry is stagnating on account of the legal prohibition against assessments on mining stocks, shall be declared raised.

There are many mines about Butte, and for that matter all over the Territory, that would be adding to the general prosperity of the country if they could by any means be developed to the point of production. There are plenty of mines in the country owned by poor men who would gladly surrender a portion of their property for the sake of having the remainder made valuable. The men of this region are out here to take chances. The most of them would take stock in promising undeveloped property, and pay in their assessment of 10 or 15 cents per share like little men, if the opportunity were given them. A very large number of laboring men became wealthy in Nevada by such means in early days. It is to the interest of men having money invested in realty, and to men in business in proximity to mines, that their investment shall be enhanced in value, and their business augmented by the development of such mines. Every man doing business or living in Butte is interested that every mine in his neighborhood shall be giving employment to somebody, or adding something to the wealth of the country.

The non-assessable stock plan has been tried and found wanting. The men holding stock in mines organized under the corporation law, however anxious they may be to see development going on, are absolutely helpless. They can get nothing for their stock, and have no way of procuring means for development except by mortgage, which is sure to wipe all stock out upon foreclosure. The history of the Belle mine, one of the most promising properties in Summit valley mining district, is a good illustration of how the non-assessable plan works. The paid up

stock sold readily on the strength of the promise of the mine. Extensive improvements were made; but before the mine had commenced producing bullion the encumbrances thereon fell due, and stockholders had presented to them the alternative either to clear off the encumbrances or lose their stock. To clear off the encumbrances it was obvious that all stockholders must act in unison. If an assessment had been possible, many of the stockholders would gladly have protected their stock in this manner, the delinquents would have been sold out, and work would have gone ahead without delay. That the matter was arranged in a way that enabled investors to save a portion of their investments was no credit to the old law.

The experience of Montana in its quartz mining interest should be its guide for the future. Up to 1872, mines were held all over the country by record title. Nobody would work them, because the title was indefeasible and without condition. The rich mines of Butte were all recorded, but the place remained a dwindling placer mining camp. The law of 1872 did not become operative until 1874, from which time the prosperity of this as a quartz mining camp dates. It is safe to say that Montana was set back 10 years in development through an unwise enactment. Railroads and the later progress that has overtaken Montana would, without this fool law, have struck the Territory long before. The Legislature cannot now afford to tie the hands of one of our most important industries through unwise legislation. Give the brave hearts and willing hands in the Territory some protection for their labor and investment, that they will not be at the mercy of stock jobbing wreckers, and the wealth of the Territory will be increased and its mines developed.—*Butte (Montana) Miner.*

DEEP SPRINGS MINING DISTRICT.—Mr. S. P. Roberts, of Big Pine, sends us the following description of that portion of Deep Springs District formerly called Pine Mountain District: "This lead or galena belt is situated on the eastern slope of the White Mountains about six miles west of Deep Spring Valley, and fourteen miles (via Black Canyon) from the line of the C. & C. R. R. This galena belt is about six miles in length and from one half to three fourths of a mile in width. The formation is lime and slate. The veins run in a northerly and southerly direction, and dip to the east at an angle of about 45°. They vary in width from six inches to seven feet, with lime hanging walls and slate foot walls. Some forty-two locations have been made and there is room for many more. Thus far but little prospecting has been done, though with encouraging results. One mine has been developed to a depth of between 80 and 90 feet and shows a large and well-defined chimney of ore from 3½ to 4 feet wide; good judges say there is \$10,000 worth of ore in sight. On the same hill are two more claims which have been worked. One has a shaft 65 feet deep, showing 3½ feet of ore. Six assays from this claim average \$55.80 silver, 63 per cent lead and \$9 gold. The other mine shows a solid body of carbonate galena chloride ore 7 feet between the walls, the whole of which will work in a furnace \$53.60 silver and 65 per cent lead per ton. Eighty assays of ore from a number of claims here, made at the Standard office at Bodie, gave an average of \$50.90 silver, 48 per cent lead and \$8.60 gold. I have been engaged in handling lead ores for the past 16 years, have visited most all the leading lead or galena camps on this coast, and will say that the outlook here, for the amount of work done, is 50 per cent ahead of any camp I have ever seen. It is the right formation for lead ores. Here are thousands of acres of nut pine timber which can be utilized in making smelting coal. The summits of the mountains are covered with a heavy growth of tamarac from 6 inches to 3½ feet in diameter and from 20 to 60 feet in height. There is an abundant supply of good water, also iron, fire clay and, in a word, every facility to smelt and reduce these galena ores. There are no rebellious metals to contend with. The country is easy of access.—*Ingo Independent.*

COMET DISTRICT.—During the week reports of big strikes and samples of rich ore were brought into Pioche. The claim owned by Col. Jack O'Brien and Rafe Barton have now about three feet of good ore, with a very rich streak, four inches in width, running through the center of it. Assays from samples of this rich streak brought to town showed \$1,600 and \$2,300 in silver. Barton claims that the ledge will average \$500. We learn from Charley Hopkins, who returned from Comet during the week, that John Ince has opened up on his claim a cave, or what appears to be a natural tunnel, of ore, about three and a half feet in width. This ore is soft, but there are large chunks of carbonate ore through it, large chunks having been taken out. Two assays made of this ore by Hopkins Thursday afternoon went \$144 and \$183 in silver. The owners of this claim, we believe, are Jno. Ince, Ed. Freudenthal, Steve Draghevitch and Dave Kent. Ed. Pierson and Jim Clark have also discovered a claim with very favorable indications. Owing to these and several other discoveries made in Comet District, quite little excitement is existing in regard to this locality. The formation of the district is white lime, and everything that has been discovered is yet on the surface. We hope the work of development will prove as good as the sanguine expect. Where there is so much rich ore on the surface, it is natural to suppose there is a big mine somewhere in the locality.—*Pioche Record.*

MECHANICAL PROGRESS.

Strength of Timber.

Timber from the heart of a tree is stiffer than the sap-wood; that from trees of average age than that from old trees; well-seasoned timber than that of green, and generally the stiffness increases with the weight, or rather the specific gravity. The same rules apply to the strength of the timber. If the quantity of timber be the same, the stiffness of a beam will increase with its depth, but care must be taken not to make it so narrow as to incur the danger of tipping over. Hence, to determine the size of a beam to be fixed at both ends, a series of rules are given, one of which will serve as an example.

Rule.—When the breadth, length and weight to be sustained are given, to find the depth.—Multiply the square of the length in feet by the weight in pounds, and this product by a number varying according to the kind of timber (in the case of good white pine, it would be about .025). Divide the product by the breadth in inches and the cube root of the quotient will be the breadth in inches. Rule for finding the breaking weight of a piece of timber: Multiply the breadth in inches by the square of the depth in inches. Divide the product by the length in feet, and the quotient, multiplied by a "constant," depending upon the kind of wood, (for white pine about 650), will be the weight in pounds. If the timber be supported at one end only, but one fourth of this weight would be required to break it. If the weight be uniformly distributed over the beam, it will require twice as much to break it as if the load is collected at the middle.

A force tending to compress a pillar or other piece of timber may operate in several ways according to the height and thickness of the timber. If its height be great in proportion to its diameter, it will bend, and if the weight be sufficient, break at the middle. This will be the case if the height be greater than 30 times the diameter. If, however, the pillar be short, it will be crushed. As concerns its power of resistance to crushing, the seasoning of wood makes a great difference, as wet wood has little more than half the strength of dry. For strength in this particular, good oak is to be recommended, after that pine. The strength of a long pillar is about three times as great, if the ends are flat, as if they are rounded. Giving pillars a bulge at the middle somewhat increases their strength. Of course, short pillars are much stronger than long ones. A column of pine 14 inches high and 14 inches square, has been known to support a weight of nearly 1,000 tons.

If wood be strained lengthwise, its power of resistance will vary directly as the area of its cross section and inversely as the length of the piece and the force employed. This holds true as long as the elasticity is uninjured, but after that is impaired, the strength of the timber is materially less. The weight required to overcome the cohesion of pieces of oak about a foot in length with a cross section of one square inch varied between 18,000 and 20,000 pounds. A similar piece of pine was pulled apart by a force of about 13,000 pounds.—*Wood Worker.*

MACHINERY AND LABOR.—Some men, especially mechanics, never seem to be able to learn the lesson that a slow machine is often cheaper than a fast man. The other day, when talking with a very expert machinist in regard to a certain job of work, he said that he could do it in 15 or 20 minutes any time, and in about half the time which it would take the ordinary machine to perform the same job; but he forgot that he is worth about \$4 per day, while the machine and the boy to run it is probably not worth more than half as much. The complaint is often heard that planer hands, lathe hands, drill press hands and special tool men are driving out the good and expensive machinists; that the boy learns to run a drill press, and so takes the bread and butter out of the mouths of men who not only know how to handle a drill press, but to make it, as well, if necessity comes. The fact is forgotten that when the drill press is simplified so that a boy can do a certain class of work on it, a great many extra boys and drill presses can be employed doing work which it would never pay to do if the first-class machinist had to furnish the labor. The machinery in such cases lifts boy and machinist together. The man that has the brains and skill is taken where his brains and skill are of the most value, and the day laborer finds himself in a better position than before. Instead of turning a crank to furnish power, as was the fashion years ago, he has advanced several steps, and is, perhaps, at a drill press or an emery wheel, or doing a class of work considerably more valuable than that which he would have had in the last generation.

AN IMPROVED HORSESHOE.—A patent has been taken out for a horseshoe made by pressing cow-hide into a metallic mold and then treating it with a chemical preparation. It is claimed that this shoe can be put on so tightly that neither water nor dust can get between the hoof and the shoe; that its elasticity makes the horse's step surer and lighter; that it is more durable than the ordinary shoe, requires no calks, never injures the hoof, and is, of course, much lighter than the metallic shoe.

A Walking Power for Street Cars.

Another factor has appeared in the attempts to cheapen the cost of running street cars, and thus proportionately reduce the rate of fare. This time it is a motor invented by B. C. Pole, an engineer of large experience in the service of the United States Government. The motor does not employ steam, and it weighs only 4,000 pounds, a weight easily carried by the street rails now in use. The force is derived from an Otto or similar class of gas engine, into which coal gas is fed from a tank or reservoir. After its injection into the engine it is exploded, and this explosion, operating upon a series of pumps or valves, sets in motion the movements of the motor. In the first place, there are two fluid cylinders so arranged as to bring the pressure of the fluid upon a foot, which goes down upon the cobbles between the tracks, making a step of three feet two inches in length; and every time this grip-like device, fitted with teeth, and nicely adjusted for securing purchase or hold, makes a step, the motor is propelled or pushed forward three feet two inches, the steps to be decreased or increased by regulation from the engineer. The foot is padded with rubber, which gives its stroke upon the earth such elasticity that there is no jar or sudden start.

Immediately over the top of the foot as it rests on the earth are two air cylinders connecting with the feet by a swinging shaft. Upon these feet they bear a pressure of 500 pounds. The action of the air and fluid pressure is simultaneous in effect, and when the power of propulsion by the latter has been expended the former lifts the feet, and the counter action of the hydraulic cylinders takes them forward for the next backward or propelling movement. The operation of the machinery is described to be as simple as the movement of an elevator.—*Philadelphia Record.*

CUTTING SLOTS IN IRON BARS.—Our readers are more or less familiar with the work of the "fusing disk" used for cutting iron bars in rolling mills and elsewhere, but we are confident that the following from a correspondent of the *American Machinist* will prove novel to most of them. Having to cut a slot one inch by two and one fourth in the ends of a large number of steel bars three eighths inch thick, he thus describes his mode of proceeding: "First, I drilled an inch hole two and one fourth inches from the end. I then took out my emery wheel and put in its place a disk 12 inches diameter, No. 14 sheet iron (scant one eighth inch thick.) I also made a table with a gauge to rest the fly bars upon, with a lever at the back end to press the bars to be slotted against the revolving disk. I made two slots at each end with the wheel, cutting to the hole. I cut them at the rate of a trifle over four inches per minute (made 18 cuts in 10 minutes). I also found that when I run the edge of the disk in water it cut twice as fast as when I ran it dry. The motion of the disk was 2,800 revolutions. I think a higher speed would have made quicker work, but I could not speed it any higher without making changes in my pulleys, which I did not care to do, as it worked very satisfactorily as it was."

IMPORTANCE OF LITTLE THINGS.—One of the most difficult things to make an ordinary mechanic understand is that two things cannot occupy the same place at the same time. It is consequently a never ending source of wonderment to him when he finds that lace, a gelatine film or a pressed flower can be made to give an impression in lead, or even in soft steel, when passed between the rollers of a transferring press. That the soft substance can indent the hard one taxes his credulity to the utmost; and when he sees the work done, he is ready to disbelieve his own eyes. When such a man finds the print of a hair on his cold forging, or a thousand and one other instances illustrating this fact that two substances cannot occupy the same space at the same time, his wonderment exceeds all bounds, and yet, though slow to believe such a demonstration as this, it is easy to accept the fact that a little water on a piston may be sufficient to smash the cylinder or blow off the head, which is only another illustration of the same fact.

POWER ABSORBED BY BRAKES.—On the Metropolitan Railway of London the stations average but half a mile apart, and although the engines are as powerful as those on the Great Northern railway, while the trains are far lighter, the average speed attainable is only 12 miles an hour. No sooner has a train acquired a reasonable speed than the brakes have to be sharply applied to pull it up again. As a result of experience and calculation it is found that 60% of the whole power exerted by the engine is absorbed by the brakes. In other words, with the consumption of 30 pounds of coal per train mile, no less than 18 pounds are expended in grinding away the brake blocks, and only the remaining 12 pounds is doing the useful work of overcoming frictional and atmospheric resistances.—*Ex.*

HOW TO TEMPER A SMALL SPRING.—Heat the spring to a light red, dip it in water, not too cold, then make a small fire with some fine shavings and hold the spring over the flames until it becomes black all over; then hold it in the fire until the black coating disappears. The spring must then be swung in the air until it is almost cold.

SCIENTIFIC PROGRESS.

Mr. Edison on Storage Batteries.

A representative of the Boston *Sunday Herald* called upon Mr. Edison some time ago, with the object of ascertaining his views upon the electric light in general, and the outcome of the interview furnishes some very interesting reading. He seems to think, and many others with him, that the so-called storage batteries, whereby electricity is to be delivered to consumers, all really bottled up and ready for use, is a delusion and a snare, when commercially considered. In the course of the interview he made use of some very plain language, a portion of which we reproduce. Mr. Edison said:

"The storage battery is, in my opinion, a catch-penny, a sensation, a mechanism for swindling by stocking companies. The storage battery is one of those peculiar things which appeal to the imagination, and no more perfect thing could be desired by stock swindlers than that very self-same thing. In 1879, I took up that question, and devised a system of placing storage batteries in houses connected to mains, and charging them in the daytime, to be discharged in the evening and night to run incandescent lamps. I had the thing patented in 1879 (I forget the date of the patent), but there is nothing in it. I rung all the changes on it. My plates were prepared like Plante's. The method of preparing them for charging is more tedious, but it is better than that of Faure, after preparation. You know the first storage battery was sent from France to Sir William Thompson, who was at first astounded by it. He was asked to endorse it, consented and took a retainer, but on investigation he became convinced that there was nothing in it, and returned the retainer to the French company. The fact is, the more he investigated the more he found out the fallacy of the whole business. On account of what Labouchere calls a swindle, this secondary battery has been used by the arc companies of England. One company alone, on the strength of an accumulator and an incandescent lamp copied from mine, floated subsidiary companies, whose aggregate capital was over \$30,000,000, and immense sums were paid by these companies to the parent company for rights. Within the last few months the bubble has burst, the shares, upon which \$25 have been paid, are offered at \$1, and the swindling companies have been sued for making misrepresentations in their prospectuses, and judgment has been recorded against them.

Scientific storage is all right, but commercially an absolute failure. You can store it and hold it; but it is gradually lost, and will all go in time. Its efficiency, after a certain number of charges have been sustained, begins to diminish, and its capacity and efficiency both diminish after a certain time in use, necessitating an increased number of batteries to maintain a constant output. Owing to corrosion of the sustaining plates of the battery, the effect of local action and other causes, too many to enumerate, the yearly depreciation of the battery is not less than 30 per cent. of its first cost, if used daily.

I will tell you where the fallacy in this arrangement lies. It consists in the fact that the cost of batteries to store this extra electricity that could be produced in the daytime would be twice as much as the station that produced it; so that, if the company has already invested \$100,000, and agree to utilize their machinery in the daytime, by the addition of storage batteries, they will find that to carry out their desires it will cost them \$200,000 for the batteries. I will guarantee that not one board of directors in a hundred will see it, and the parent concern will not tell them of it until after they have purchased. It seems to be natural with boards of directors, that if there be a wrong way to do a thing they will surely do it that way.

Astronomical Distances.

In a recent lecture on astronomy, delivered by Prof. C. A. Young, the lecturer made use of the following very striking illustrations to convey an idea of celestial distances:

"We have been able to make out pretty certainly the size and dimensions of our own earth. That is not so very difficult. We have reached out further, and now we are able to tell with considerable accuracy very nearly how far away and how large the sun is. We are trying to reach out for the stars. We cannot tell exactly how far they may be, but we know that our nearest neighbors are at a most tremendous distance—beyond the reach of human conception. The earth is about 8,000 miles in diameter. If you could make a straight railroad around the equator, it would take just about 26 days to make the circuit of it, at 40 miles an hour, without any change of stations. No practical means of conveyance will take you around it in less than three months. Then the moon, our next neighbor, is about thirty times as far away as the earth's diameter—about 240,000 miles. That is not so very inconceivable. When we come to the sun, we find its distance is about four hundred times as great as that of the moon, about 95,000,000 of miles.

"Those figures mean nothing until you take an illustration. Take a railroad from the earth to the sun, with a train running 40 miles an hour without stops, and it would take about 265 years and a little over to make the journey. So that, if the first settlers of this country, at

the time they started from the mother country, had started from the sun by this railroad, they would be just about reaching this country now. But very few of them could have afforded it, for even at a cent a mile the fare would have been \$950,000. There are very few people, even in New York, who could afford to go to the sun at that rate of cheap fare. But when we come to consider the nearest star, whose distance is two hundred thousand times as great, we can do nothing with it, even in our imagination. If we should count the money that it would take for a railroad journey to it, even at a cent a mile, it would come to two hundred thousand millions of dollars—a hundred times the amount of the national debt of the United States."

The Origin of Petroleum.

Mr. Max Livingstone, in a paper lately read before the Western Society of Engineers, made the following remarks on this interesting subject:

"To explain this, in the highest degree interesting and important question, theories without number have been propounded, but although men eminent in scientific circles have wrestled with the problem, we are far from a satisfactory solution. For this reason, it would be more gratifying to myself to dismiss the subject as to embryonic, were I not conscious of the curiosity which many of the gentlemen present feel to hear something, no matter how hypothetical, regarding the formation of petroleum.

"I shall but briefly refer to a few plausible theories. According to one, the oil is indigenous to the sand rock, and is supposed to have been elaborated by nature from organic matter, which, during the paleozoic ages, when submarine plants and premodern animals flourished in abundance, were deposited simultaneously with and in the sands. But when, and by what means these hydrates and mollusks could have been converted into oil so completely that not even a trace of them has been found, and how this oil, during incalculable ages, subjected to revolutions of the most violent character, could have been preserved is beyond our comprehension.

"Diametrically opposed to this hypothesis is the theory that oil is a product of condensed gas, distilled, so to speak, at a great depth, where the temperature is sufficiently high, from organic deposits in the beds of the silurian and devonian formation. The gas thus generated is forced to the upper and cooler strata, where it is absorbed, and, as far as possible, condensed into liquid in the sponge-like reservoirs—the sandstones. Analogous to this, only combating the organic origin, is the theory propounded by Prof. Mendeleeff. Calling into requisition the nebular hypothesis of Kant and Laplace, and assuming that the interior of the earth contains large masses of metal and carburetic compounds, he draws the following conclusion: "Through some of the fissures in the crust of the earth, occasioned by the upheaval and depression of the surface, water percolated to the carbureted metals and acted upon them at high temperature and elevated pressure, thus forming metallic oxides and saturated hydrocarbons. The latter rose in the form of vapor and became converted into liquid, as before described.

"But all these theories have many vulnerable points, which to expose at this time would lead us too far. Neither can I spare the time, nor have I the inclination, to speculate on the probable amount of oil likely to be produced yet, until the explored oil territory has been drained. Experts have given us figures and opinions, supported by ingenious arguments, which in many instances were refuted before the printer's ink had time to dry. The oil territory, distributed all over the globe, is so vast that we need not fear its early exhaustion, and I venture to assert that its classical domain, so to speak, will for some time to come be the State of Pennsylvania."

MINERALOGICAL NOTES.—In a late "Contribution to Mineralogy," Prof. Genth, who possesses to an eminent degree the ability to discuss the important questions involved in the chemical changes taking place in the mineral kingdom, has added a number of important facts to science on the subject of alterations in mineral, which he has made a special study, and of which the present paper is but a continuation of others that have already appeared. Prof. Genth describes in this contribution the partial alterations of corundum, found in Madison county, North Carolina, into massive greenish-black spinel. He notes the occurrence of a pink corundum from Towns county, Georgia, surrounded by greenish white cleavable zoisite; also the alteration of corundum into feldspar, near Media, Pa., and similar alterations of corundum (also into mica) were observed in specimens from Heywood county, North Carolina. The author also notes the alteration of corundum into margarite, fibrolite and cyanite, and describes examples of these. The following are also among the interesting alterations noticed by the author, viz., orthoclase into albite; talc into anthrophyllite; and pseudomorphs of talc after magnetite. The paper, besides several special investigations on other minerals, records the interesting observation of the accidental formation of artificial crystals of rutile during fusion with potassium hydrogen sulphate; two crystals of octohedrite showing a decided blue color, were produced at the same time. These investigations have an important bearing on the genesis of a number of mineral species.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

ASSESSMENTS—STOCKS ON THE LISTS OF THE BOARDS.

Recent Contributions to the California State Mining Bureau.

[CATALOOUE.]

4564. Selenite, Gypsum—Near Modesto, Stanislaus Co., California, L. Figueroa.
4565. Brown Stone, Freestone, (of which New York is largely built)—Coppercut, M. Haverin.
4566. Copper—Copper King Mine, Emeralds, Nevada.
4567. Wall Rocks of the Copper King Copper Mine—No. 4566, Emeralds County, Nevada.
4568. Gneiss, Borax, Eagle Borax Mining Co., Death Valley, Inyo County, California, D. Auer.
4569. Refined Borax—see No. 4563—Eagle Borax Co., Death Valley, Inyo County, California.
4570. Sesquioxide of Iron, Göttsche, (?), with Microscope slide this mineral is in beautiful hexagonal plates—Near Lamoine, Elko County, Nevada, Arthur T. George. A similar mineral is found at Pioche, Lincoln County, Nevada; see No. 4571.

THE STEAM PLOW.—A correspondent of the *Stockton Independent* gives this succinct report: I saw the steam plow work yesterday. Engines, two; distance apart, 460 yards; width of land plowed at each passage, four feet; number of plows used, eight; four used at a time; there should be five, making 10 in all, but two are being tempered; time of cutting a furrow, from four to five minutes; power of engines each, 40 horse; character of land, tough, black soil, salt grass growing; depth of furrow, six inches; every part of the machinery working well; cost of fuel, five dollars per day for both engines; capacity, from 40 to 60 acres per day in sandy soil. The writer is of the opinion that, with very few alterations on the plows, the machine will prove an immense success, and will supply a long-needed want for plowing land in California. Land plowed by this machine will produce at least one fourth more crop for a period of six or seven years than by the ordinary plowing in use in this State.

THE new charter for San Francisco was defeated at the election on Saturday.

FOR tremulousness, wakefulness, dizziness, and lack of energy, a most valuable remedy is Brown's Iron Pitters.

4672. *Selenite*, Gypsum—Calico, San Bernardino County, California, John Daggett.

4673. *Lava*—which exists in immense quantities on the borders of Mono Lake, Mono County, California, Owens River cuts through this formation in a deep canyon. It is easily decomposed and supposed to yield the Soda Salts so abundant in that region. It occurs also at Adobe Meadows, in Mono County. It is well worthy of a critical examination.

4674. *Vaiegated Obidian*—Near the South end of Goose Lake, Modoc County, California, F. H. Merrill.

4683. *Fluorite*, fluor spar with calcite—Cumberland, England, J. Z. Davis.

4684. *Selenite*, gypsum—Near Modesto, Stanislaus County, California, J. Z. Davis.

MISCELLANEOUS.—Amador *Ledger*, March 3: The Empire mine is adopting the Frue concentrators. Sixteen are to be placed in the 80-stamp mill. The satisfactory results obtained from those in operation at the Pacific mill, have led to their adoption at the Empire.

SEASON.—This mine pursues the even tenor of its way. It employs from 15 to 20 men, and distributes in wages and other expenses about \$3,000 per month. Mr. Symonds is superintendent, and seems to be running it very judiciously. The monthly yield has been sufficient, so far, to pay expenses, and the employees receive their money regularly every month. The mill has been kept running on rock from the tunnel, but it is probable that sinking will be undertaken in a short time.

BUNKER HILL.—The personal property under attachment was sold by the sheriff, last Saturday. It was sold to Mr. Haven, the representative of the company, for \$3,520, the amount of the judgments and costs. There are no attachments on the property now, except one for \$18,000, but this was put on by parties who are stockholders, and will give no trouble in getting the property out of the legal tangle in which it has become involved. The only incumbances now to be disposed of are the mechanic lien holders. A proposition was submitted by the company, that they will proceed to work the mine, and agree to pay the back wages in four monthly instalments, the first instalment to be paid April 1st, and the working expenses to be paid regularly every month. The employees held a meeting in the early part of the week, at Amador City, to consider the proposition. It is likely that the offer will be accepted, though perhaps in a somewhat modified form.

PARTIES are putting up a 10-stamp mill on the Loyal Lead property, in Black Hills, near Drytown, for the purpose of crushing rock from the old Loyal Lead tunnel. It is thought by those acquainted with the claim that this venture will pay.

THE Median mine, adjoining the Keystone, is likely to be started up this spring.

W. A. NEVILLS, on his trip to San Francisco last week, took down, so rumor says, from 70 to 80 pounds of bullion, the product of the bonanza in the Mammoth lead.

MR. GOODMAN is at Quartz Mountain, for the purpose of arranging to recommence operations on the Quartz Mountain mine.

MAHONEY.—The complications in which the affairs of this mine have become involved are still unsettled. H. H. Town, who went below to confer with the managers of the company, and also to make arrangements with creditors in the city, returned a few days ago, and reported favorably of the result of his trip. There appears no obstacle in the way of the working of the mine as far as parties below are concerned. The creditors here, however, seem to be a little disappointed on being notified by Mr. Stewart, the superintendent, that he will want something to say in regard to the manner in which the mine shall be worked. The employees have filed liens to the number of over 60; but this will not necessarily invalidate the continued idleness of the mine. It is understood the intention is to have the necessary legal proceedings between the company's agent and the creditors, with a view to the immediate resumption of work. Judgment was obtained last Saturday against the company for nearly \$10,000.

BUTTE.

HYDRAULIC MINES.—Oroville *Register*, March 3: Some six or seven hydraulic mines are being worked below Oroville. There is but little fall to the ground, so it is quite difficult to run off the claims. About 20 men are employed in the various tailings, and 1,000 inches of water is used. The most important mine is that known as the J. M. Frost mine. This employs 5 men and uses 400 inches of water. In order to raise the gravel from the bottom of the mine a new patent elevator is used.

CALAVÉRAS.

WORK PROGRESSING. — Calaveras *Chronicle*, March 3: Work is progressing favorably in the Anglo Saxon mine—formerly known as the Beaver mine—situated about three quarters of a mile southeast of Rich Gulch Flat. A shaft has been sunk on the lead to a depth of 100 ft, at which point a level has been run 60 ft in length, displaying a fine body of ore. A small quantity of unsorted rock was taken out and sent to San Francisco, where it was assayed, and yielded at the rate of \$150 per ton. The mine paid well in former years; the lead is wide and well developed, and the rock carries considerable free gold. The mine is under the superintendence of J. W. Meyers, Esq., a gentleman who thoroughly understands his business, and there is not the least doubt but that under his regime the Anglo Saxon will develop into a permanent paying property.

WESSON MINE.—The work of clearing out the tunnel on the Wesson mine, situated about a mile from this place, is progressing finely. The tunnel, which was badly caved in some places is being cleared of its debris and retimbered, preparatory to further developments.

EL DORADO.—*Mountain Democrat*, March 3: Superintendent Fred, Jones, at the new mill he has recently erected near Shingle Springs, recently crushed about 15 tons of ore from the claim of Bosquist, Honx & Gray, and the yield amounted to about 590 per ton. They have about 40 tons of ore somewhat inferior to this that they will have Jones crush next week.

PROSPECTING.—Georgetown *Gazette*, March 3: During the winter Robert Cushman and son have been prospecting some deep gulch ground a short distance to the north of their residence, meeting with flattering prospects. A few days since, they began sluicing, and it is thought they have a good claim. We hope this is so, for Mr. Cushman is deserving of a rich find.

A FEW days since Watson & Keefer shipped several hundred pounds of copper ore from their mine near Garden Valley to San Francisco, for further test of its value. Smaller quantities of this ore, previously assayed by Prof. Thos. Price, gave results highly satisfactory. That the ore just shipped is equally as rich in copper, silver and gold, no one acquainted with the ore will have any doubts; and further, should the present test prove anywhere near the former assays, it will demonstrate to a certainty that this mine is a valuable property, for the reason that the lode is large and continuous.

THE ditches of the California W. & M. Co. are now running to their full capacity, and we believe all the water is being used by our miners. Mining interests appear to be more active this spring than usual. A new life has taken hold of our people. The severest spell of "hard times" ever experienced on this divide during the winter just ended, seems now about to yield to a season of more than usual prosperity. In addition to the mines already under heading, we hear of quite a number of important mining enterprises which will be started up during the present season, on this divide. Among these may be named the Eureka and Woodside, in this place.

MILF KNOX evidently has struck good diggings; he has started in with 40 inches of water.

BALLARD & WARREN have started up the Gopherhole mine in this place.

GEO. HANBY is engaged in getting out chrome ore, on the serpentine belt southeast of town.

SINCE the thaw, work has been resumed on the Bob Redd mine in full force, and they are taking out specimen ore rich as ever.

SMEDER & FORNI are pushing their tunnel night and day. They have already cut a stringer which prospects well, and expect to tap the main lode some time this month.

S. HANSON, after being shut down for so long a time by the cold snaps of the winter, has started up the old Parsons mine and mill in good style, and we confidently expect that he will take out big pay this summer.

BILL LANE has a seam claim below town, from which he has been obtaining prospects sufficient to induce him to have it worked, and John Bennett has consented to take hold with him and work the mine. Bill has faith in the mines, and well he may, for it's the mines that keeps our business men on their legs.

FRESNO.

GERTRUDE.—Cor. Mariposa *Herald*, Mar. 3: This camp at present is quiet. The Enterprise mine and mill suspended operations two weeks ago, which, in consequence, makes this place very dull. I learn from reliable authority, that the suspension of the Enterprise mine is only temporary; that the mine is looking as well to-day as it ever did, but that the formation—slate—has become so hard and expensive to work that the company desired to suspend operations until arrangements could be made to obtain machinery that will enable them to work it to better advantage and at less expense. Operations will undoubtedly be commenced at an early day—at least we all hope so.

NEILS. ESTERSON has just uncovered a rich chute of ore in his Fresno mine, situated on Potter Ridge, near the Enterprise mine. The ore taken out so far is fully as rich as any ever taken from the famous Enterprise. The vein or ledge is rather small on top, but it increases in width as it goes down.

THE McDonald Bro.'s mine, at Grub Guleh, is still idle, waiting for rain, so they can start their mill. I understand they are making arrangements to bring in water from the Fresno river, which will give them abundance of water. Water is the only thing lacking to make this one of the best bullion producers on the coast.

CAPT. HARRY BERRIMAN is engaged in taking out some very rich ore from his Wellington mine, and will doubtless realize good profits therefrom.

NEVADA.

MT. AUBURN MINE.—Nevada *Transcript*, Mar. 3: Affairs at the Mt. Auburn mine are getting along nicely under the superintendence of that veteran gold digger, Capt. White. From 12 to 14 hands are constantly employed, and about 18 tons of ore per day is the output. This comes from the 360 and 460 levels, the latter being in much the richer ground. For a new property the Mt. Auburn shows up splendidly, but like any other, it must be thoroughly developed before it can be expected to pay dividends to its owners.

A GOOD PROSPECT.—The McCutcheon mine is now under the management of Charles H. Crosby, and the work on it is progressing finely. An incline is being run down, and the rock continues to look first class. A gentleman who visited the mine a few days ago informs us that he believes within six months the new company will take out, over and above all expenses, the amount that was paid, and have the claim. The price paid for the mine was \$10,000.

PLUMAS.

GREEN MOUNTAIN MINE.—Greenville *Bulletin*, March 4: The mills of the Green Mountain mine were forced to stop on Wednesday evening of last week, the water supply being exhausted. At the present face of the drift in the tunnel there is a heavy down-pour of water; while this is very unpleasant for the workmen, yet it does not occasion any loss of time. It is expected that when the tunnel is advanced a little further, this water streak will be left behind and the ground again become dry. Immediately after the mills were stopped, it was inferred that all of the machinery must stop, but this was a mistake; enough water has been supplied to furnish power for running the air compressor so that work in the tunnel has not been interrupted; the ventilating fan is in operation, and the work is going on more rapidly than before.

MICHIGAN HILL.—Robert Martin was over yesterday from Michigan Hill after a lot of iron bands made at the foundry here for the water pipe at his hydraulic claim. These bands are to prevent the pipe coming apart at the joints; the pressure is 200 ft head, and even in this dry season Mr. Martin is confident of having water enough for a four months run; the supply is brought from the mountain on the north side of Spanish Creek, the pipe being carried across the creek on a bridge built for that purpose. The partners own 120 acres of mining ground all of which was prospected before the present pre-

parations for working it were begun. Years ago the late ravines on Michigan Hill were worked by the old method of rockers, and a great deal of gold taken out, with the improved appliances of the present owners of the ground the prospect is good that they will be successful.

TAYLOR-PLUMAS MINE.—Like most of the other mills around, the mill of the Taylor-Plumas is still idle for want of water; in the mine most of the work lately done has been confined to the winze; the drift here has been steadily pushed eastward with good prospects as the work advances. A few hands were put to work last week in the face of the main tunnel, the ground here gives indications of becoming softer, and according to the usual experience the ledge may be expected to widen out.

INDIAN VALLEY MINE.—The Indian Valley mine is running steadily by steam power; an addition of 12 miners was made to the working force this week.

SAN BERNARDINO.

PROVIDENCE MINES. San Bernardino *Times*, Feb. 24: As I wrote you in a former letter, the bullion output for the month of January, from the Bonanza King Con. mill, was over \$61,000, and in all probability it would equal it this month. There has been already run 15 bars, value over \$23,000, with sufficient amalgam in the mill to run 10 bars more of equal value. Although it is likely that the mill will not make over 23 days on Bonanza King ore this month, it will probably reach the last month's production of 31 days. No 10-stamp dry crushing mill on the slope has shown such results, and the company are to be congratulated on having such an able metallurgist as Mr. E. Huhn; not only has the percentage run very high (over 80%) but the fineness of the bullion is seldom equaled (with the same class of ore), averaging over 930 fine for the past week.

THE BELLE MCGILROY MINE.—Had something like 25 tons of ore worked by the Bonanza Con. this month. It is said to have run up in the hundreds. The owners, Messrs. Dwyer & Gorman, have already refused \$50,000 for their mine. They are pushing their works down with large showings of fine mineral.

MR. R. P. KERR is opening his mine north of the Bonanza King, which is showing up a considerable quantity of high grade ore. There are now sunk two shafts, one some 50 ft, and the other about 25 ft with several openings along the ledge. In drifting from the bottom of one of the shafts he is taking out some high grade ore, with fine prospects ahead.

THE LUCKNOW MINE, south of the Belle McGilroy, were shown several assays running in the neighborhood of \$700 per ton. The owners have run across a ledge of about 10 ft, carrying mineral the full width. There are several other small openings on this claim making a nice showing of mineral.

A NEW STRIKE was made during the past week, between the Bonanza King and Rattler. The shaft is now down some 12 ft, with every prospect of a fine body of ore. The company, also, in sinking a winze in the south end of the mine, struck another body of fine mineral, taking out 49 sacks of ore in one day, assaying over \$750 per ton.

MR. J. K. PATTON, of this place, has purchased from Messrs. Kenniston, Brazelton & Folks one of their stages, with six of their best animals, and will in the future run from here to the end of the track, so that all parties coming to this place can jump on the cars and be here in a few days without any inconvenience. Good miners will find employment, wages \$4 per day.

SIERRA.

THE SIERRA BUTTES MINE.—Sierra County *Tribune*, Feb. 29: At the Sierra Buttes mine a vast amount of dead work is being done at present. Number 9 tunnel is in a distance of 2,200 ft. The company have had some very hard rock to contend against in this tunnel, which has made the expense of running it greater than was anticipated. An outlay of a great many thousand dollars will be required before any benefit can be derived from this part of the mine, and no doubt many smaller companies would fail to carry out such an immense amount of work as is laid out to be accomplished by this company during the coming three or four years. The Sierra Buttes mine is a standing advertisement for Sierra County. The successful working of a mine to such a great depth as will be reached on this ledge when the lower tunnel is in, will prove of almost an incalculable benefit to the quartz mining interests of our county.

MR. SHAW, General Manager of the Marguerite property, says that the mine is looking splendidly, and from the present outlook will yield largely the coming year. The 20-stamp mill is running regularly. The appearance of the plates indicate that the ore is paying well.

Good gravel is still found in the Ruhy mine. Some of the workmen will be discharged until room is made in the new breasts that are being opened out.

J. BURNHAM, Superintendent of the American Hill mine, who was in town Sunday, says that the snow will average three feet in depth on the ridges. Water has commenced to run and the monitors were put to work on the 22d inst.

THE report comes from Howland Flat that there is every indication of the miners having 60 or 70 days' water season in that section.

THEODORE WARE & Co., cleaned up over \$200 last week, in their placer mine at the Sweetwater ranch, on the North Fork.

A. L. MURPHY is working the old Atwood mining claims in Rattlesnake Canyon, and is doing well.

HEAVY EXPENDITURE.—The total amount expended in prospecting the Bald Mountain Extension mine, located at Forest City, up to this date, is about \$89,000. Of this sum, \$59,000 has been paid in assessments. This is a pretty heavy drain on the owners, who are principally men of moderate means. However, they have an abundance of grit, and confidence in the value of the property, and believe that pay dirt will be encountered again in a short time.

TRINITY.

TOO NICE.—*Journal*, March 3: If you don't believe there is such a thing as too much of a good thing, just interview some of our hydraulic miners as to their views regarding the present extremely pleasant weather. Unquestionably, pleasant weather is a good thing, but it is just as certain that we are having altogether too much of it for miners' use. Snow, rain, slish and mud would be infinitely preferable now to sunshine and dusty streets.

TUOLUMNE.

PROSPECT.—Tuolumne *Independent*, Dr. Congdon, of San Francisco, has struck a very fair prospect on Phil Stoner's Webster claim, and present indications are that a large pocket will be taken out. A shaft about 8 ft from the surface has been sunk. The rock thus far is well charged with fine gold—and the last work done, very coarse gold is coming in. This is a parallel ledge to the Webster, and Stoner has made arrangements with the doctor to work this partierth claim on shares.

Nevada.

WASHOE DISTRICT.

OPHIR.—*Enterprise*, March 3: The station in the joint Mexican winze is completed, and the guides are all in place for the second line of hoisting cages. These cages will be in operation and an east cross-cut started from the 3100 station about Monday.

MEXICAN.—The work of putting guides into the second hoisting compartment of the joint Ophir winze from the 2900 down to the 3100 level is completed.

HALE & NORCROSS.—The north drift of the 2600 level, joint with Savage, is making good progress. Some seams of quartz are beginning to appear; but, as yet, they carry little ore.

YELLOW JACKET.—Are shipping about 70 tons of ore per day.

GOULD & CURRY.—The west crosscut on the 2300 level is making rapid progress in vein porphyry, with occasional small seams of clay and quartz.

CALIFORNIA.—On the 2000 level the main south drift is being advanced at the rate of about 20 ft per week.

SIERRA NEVADA.—The east crosscut on the 2700 level still continues in the cross course or cross vein. The joint Union Con. east crosscut on the 2900 level is still in a compact vein porphyry.

UNION CON.—The joint Sierra Nevada east crosscut on the 2900 level is still being advanced in compact vein porphyry. The joint Mexican east crosscut on the same level is cutting occasional stringers of metal-bearing quartz.

PINTO DISTRICT.

The main incline at the Fair Play mine on Alhambra Hill in down 140 ft, with a fine ledge formation of quartz and lime, containing all grades of ore at the bottom from 15 to 20 ft thick. The Sparrow mine is a new prospect that is being opened with good indications. The croppings are plainly traceable upon the surface for a distance of 300 ft. A shaft down 30 ft on a fissure shows a galena in excellent ledge matter, and promises to make into a strong ledge. The lessees of the Silver Nugget mine are taking out some very fine ore and getting ready for a shipment. The Berryman Bros. are cleaning out the old ore chambers in the Diagonal mine on Silverado mountain, and will ship a fine lot of quartz to the furnaces as flux. This will average about \$50 per ton. The main shaft at the Western Globe on Silverado mountain is now down 120 ft from the surface and 60 ft below the tunnel level.

Colorado.

DIVES AND PELICAN.—Colorado *Miner*, Feb. 20: On Tuesday our reporter paid a hurried trip to this property. The ore is not high grade, but occurs in such vast quantities that if it can be made to net even \$10 a ton, which is a very low estimate, the thousands of tons ready to be shot down will yield a fine revenue. To confirm tests recently made, Supt. Duff this week shipped two car-loads, 20 tons, to Mr. Stevens' concentrating works at Lawson. The result we hope to announce next week. In the level below, 180 ft from the immense engine chamber, a stope is being started east of the shaft. Large ore bodies are exposed there, also. The best ore, however, at present is coming from the Unicorn, where Curtin and Reynolds in level No. 1, above the tunnel level, and Kennedy and company in level 2½, 200 ft below, are taking out considerable quantities of ore running from 100 to 400 ounces per ton. A drift on the Eagle Bird has been started west of the tunnel to intersect the drift on the same lode heretofore run through a cross-cut south from the main Pelican lode. It will have to be driven 300 ft before connection is made. Meanwhile the new drift will be chambered out immediately west of the tunnel and an engine put up with which sinking on the Eagle Bird will be pushed as rapidly as possible. This lode has produced largely in the past, and the best mining experience justifies the conviction that large bodies of rich ore are awaiting below for hammer and drill to expose them. The engine on the Perdue shaft works admirably raising the iron skip, lowering and stopping it at any desired point with the precision of clockwork. Forty-eight men are employed by the Dives and Pelican company, on company account and as leasers.

MINING AND MILLING.—*Register-Call*, March 3: A party of Chinamen—miners—left Central yesterday, with a view of effecting a lease of the placer claims on South Boulder creek, below the placer patent of the Rollins G. M. Co., worked last season by Lemmen & Co. Another party is trying to effect a lease of a placer claim on North Beaver creek.

ORE was being raised, yesterday, from the Foote & Simmons mine, on Gregory mountain. The recent purchaser of the property, Mr. Maud, will bend every energy to its development in a systematic manner.

THE United Gregory M. Co., have succeeded in lowering the water in No. 2, or the pump shaft, on the Gregory lode, to a point 65 ft below the surface. This is the first time in seven weeks that the water has been lowered to that point. The pump since being rearranged and remodeled, is working splendidly, and no fears are now entertained of any mishap occurring again through defective portions of the pump—Cornish pattern—one of the largest in use in the State of Colorado.

MESSRS. MULLEN & SATORI, contractors of this city, have taken the contract for the placement of the new and powerful plant of machinery on the Champion mine, Bellevue mountain, for the Donaldson Con. M. Co. They are also putting up an endless bucket-way from their mines to the mill and concentration works, which will be used for transmitting ore. This is a new feature in this part of Colorado for transporting ore.

SEVERAL nice gold retorts could have been seen

this morning on the cash table of Hanington & Melior's bank, in this city.

THE stamp mills of Black Hawk are well supplied with custom ore. The Empire mill is chock full, and ore piled outside awaiting crushing. The California mine company have added a portion of the Hidden Treasure mill to their stamping capacity, and the California mine, on Quartz hill, operated by them, is in as good pay at the present time as at any former period in its history. The output of the California for 1882, taking as a basis its monthly output so far, will reach fully \$300,000 in milling and smelting ore.

OWENS & JENKINS, last Saturday, shipped a quantity of ore from their new silver discovery west of the city.

SEVERAL of the gulch miners below Black Hawk are preparing to resume placer mining as early as possible in the spring. Dams have been constructed, ditches repaired, and other necessary preparations made for an active season's work.

New Mexico.

LAKE VALLEY.—*Herald*, March 3: Sinking is being done upon nearly 20 claims on Kentuck mountain, and all are giving good promise and yielding excellent assays. It is the remark of every body who examines this district, that nowhere has there ever been so high an average in the grade of ore, and so general a distribution. Mr. Dawson reports the shaft on the Comstock down 25 ft through the iron, and the crevice filled with fine quartz. This is one of the most promising claims at present. A gentleman examining our mines asked if there had been any claim jumping. On being answered no, he remarked it was probably because there was mineral everywhere, and it is not worth while to jump, any more than it is a necessity. Orders have been received to survey, for patents, the Bullion and Last Chance, and also the Little Jimmie, the former have precedence as to time. Mr. S. K. Bradford has been engaged to survey all three of them. This will bring the disputed title to settlement by proof before the Register of the land office. The policy of the Superior company is slow and sure. When development actually shows how much ore they have at hand it will be determined as to what kind of works will be necessary, and to what extent. It is of no use to be impatient. When they do decide everything will go positively and rapidly. There will be no embarrassments, no delays. Frazier, Holt & Cosgrove are now sinking a shaft upon the Savage, which lies parallel with the Superior, and which was located at the same time. It is upon the same line belt and is in contact with the porphyry upon the east of it. The line is filled with seams or veins of mineral, and it is on one of these they are now sinking, not far from No. 7 working of the Superior. The net returns from the last carload of ore shipped from the Bullion mine, to Denver amounted to \$6,170 for a little more than 10 tons. It was sufficient to pay all the working expenses of the mine for the last three months, and leave a balance of \$2,000 in the treasury. The next carload will soon be ready and the mine is yielding rapidly of high grade ore. It is a property which it is a pleasure to own.

Oregon.

NOTES.—Jacksonville *Times*, March 2: Miners of Josephine county are busy, being more favored with water than those here. Gin Lin seems to be the only miner in Uniontown precinct who has an abundance of water. Many of the miners are busy, but some have no water at all. The mining season does not promise well. Miners who have reservoirs are in better luck than ever this season, for without them they could not run at all. Goldworthy & Justus are opening the main bed of Foots creek, which enterprise will no doubt prove remunerative in time. The pleasant weather has greatly discouraged the miners, who will be unable to do much unless there is plenty of rain during the spring. The snow in the mountains is fast disappearing, much to the disgust of the miner, who looked to it as a source of supply in the late spring. The *American Mining Code*, the best work published, can be obtained at the TIMES office. Also blank notices of location of quartz and placer mines. Jas. Hansen returned from Josephine Tuesday. He informs us that Wimer & Sons are in possession of the big mine at Waldo, where operations are progressing steadily. Curtis Bros., who are engaged in pipping off the old tailings in Jackson creek, have been doing well, considering their opportunity. They took out about \$50 in one day last week. Mullen & Adams have commenced working the Rockfellow diggings this side of Ashland, and expect to make a good run. They use the water from the ditch that supplies the Ashland flouring mills until the 1st of July. Chas. Williams of Pleasant creek, who was in town this week, informs us that the once-prosperous mining camp has dwindled down to almost nothing, one white man and eight Chinamen constituting all the miners in that section. The Gold Hill M. Co. has employed Mr. Thomas, an experienced quartz miner, to prospect for the missing vein, which paid so enormously in days gone by. He had been engaged in repairing the old tunnel, which was in a dangerous condition. Bybee, Hawkett & Co. are running their claims near Waldo night and day, with good prospects. Snow fell to the depth of 3 ft at the head of the ditch and they will probably be able to run two pipes until the 1st of June, as they have excellent water privileges. A clean-up made after a few days' run yielded over \$300. Some of their ditches slid in, but the damage done is about repaired.

Montana.

LEXINGTON.—*Inter-Mountain*, March 2: For several days rumors have been afloat in this city of important developments in the Lexington mine. It was learned that, leaving out of consideration the ore recently developed on the 400 level, there is enough pay rock in sight in the mine to supply the mill for a period of two years and a half without any further exploration. On the 400 level an ore chute has been explored for a length of 120 ft, showing a body of ore of a uniform width of three feet, which samples 100 ozs. in silver from one end to the other. It is the richest silver ore chute in the district. The average ore production of the Lexington during the month of February was 55 tons. The average pulp assay from the mill was .48 ozs. in silver and .18 in gold. The output for the month (28 days) was over \$85,000, figuring silver at \$1.05.

Metallurgy of Nickel and of Copper.

The following paper on the "Metallurgy of Nickel and Copper" was read at a recent meeting of the American Institute of Mining Engineers, by W. E. C. Eustis and H. M. Howe, of Boston.

The processes which form the subject of this paper have been experimented on in the laboratory of W. E. C. Eustis, but have not passed beyond the experimental stage. The first is the invention of Mr. J. L. Thomson, of Capelton, Quebec, Canada, the others have been invented by the writers:

Thomson's Process for the Extraction of Nickel.

This consists essentially in first rendering the nickel magnetic, and then separating it from the materials with which it is mechanically mixed by means of a magnetic separator. In the case of oxidized compounds of nickel it would generally be desirable to bring the nickel to the metallic condition, in which it is most highly magnetic. The compounds of nickel with sulphur would probably, in the majority of cases, be most readily separated by bringing the nickel approximately into the state of sub-sulphide, in which condition it is also magnetic.

In most cases where nickel occurs with a considerable proportion of the heavy metals it would be best to effect the magnetic separation before fusing the material, since, on fusion, the nickel would enter into a chemical combination with the other metals present, as an alloy, matte, speise, or similar compound, from which, of course, the magnet could not separate it.

For cases where nickel occurs with a large proportion of iron, the following plan has been proposed by the writers: The either naturally or artificially oxidized compound of nickel is treated with a mixture of carbonic oxide and carbonic acid, or of other reducing and oxidizing gases, in such proportions that they are capable of reducing nickel so nearly to the metallic state as to render it magnetic, but still containing so much carbonic acid or other oxidizing gas as to be unable to reduce iron to that condition. It cannot be positively stated that it is possible in this way to render nickel magnetic without at the same time rendering iron magnetic, but experiments made by the writers render it probable that this can be effected. Having rendered the nickel magnetic, it can then be separated with the magnet from all matter with which it is mechanically mixed.

This method of reducing nickel with a mixture of gases not sufficiently reducing to render iron magnetic is an application of a general method patented by the writers.

Experiments tried with the nickel ores of Orford, Quebec, Canada, which contain a small portion of pure millerite, with calcite, pyroxene and chrome garnet, gave a concentrate containing over 60 per cent. of nickel. Cobalt would probably, in most cases, follow the nickel into the concentrate.

Magnetic Process for Sulphuretted Copper Ores.

The ores of the Crown mine, at Eustis, Quebec, Canada, contain chalcopryite, pyrite, marcasite and intermediate compounds, containing copper in every possible proportion from nothing to 30 per cent.; with these sulphuretted minerals is mixed a variable amount of silicious gangue. The writers found that, on burning these ores in heaps or in kilns, all the sulphuretted minerals became magnetic, so that, on making a magnetic separation, the whole of the copper passed into the concentrate, only a trace being found in the non-magnetic portion. Although the method is inapplicable to the Crown ores on account of the small amount of gangue which they contain, yet sulphuretted ores of copper might, in many cases, be thus treated advantageously if they contained much gangue.

The necessity of first pulverizing the burnt ore is a drawback to this as to all other methods of concentration, since the difficulty of any subsequent fusion is, of course, greatly increased by the fine state of division of the ore; it places, however, the concentrate in an excellent state for treatment in the wet way. The consumption of power in pulverizing a burnt ore is very much smaller than in pulverizing the same ore when raw, which is so much to the advantage of the magnetic separation as compared with the ordinary mechanical separation.

The following obvious extension of the above mentioned principle is proposed by the writers: Any metal existing in chemical combination with any oxide or sulphide of iron, or nickel, or cobalt, or with any other combination of either of those metals capable of being rendered magnetic, can be separated by the magnet from all gangue and other materials with which it is mixed, excepting such materials as would necessarily be rendered magnetic by the treatment which renders magnetic the metal which is sought.

The separation of gold-bearing pyrites from quartz and other gangues might sometimes be advantageously effected in this way.

Electrolytic Method for Separating Nickel and Other Metals.

This process consists essentially in the precipitation of nickel and other metals from their molten slags, on bars of iron or other metal inserted in the slag. The process of Rivot and Philipps precipitates copper from its molten slags on iron bars. Our experiments prove that not only iron, but even copper, precipitates nickel from its fused silicates, and, conversely,

that neither nickel nor copper will precipitate iron from its slags, nor will nickel precipitate copper from cupreous slags.

In the experiments, an oxidized salt of the metal which we sought to precipitate was fused with silicates of iron and lime, and with nitre, or some other strongly oxidizing flux, to insure the complete oxidation of the metal before the attempt to precipitate it was made. After complete fusion, we inserted into the slag a bar of the metal on which it was proposed to precipitate the metal contained in the slag.

On suspending iron bars in nickel-bearing slag, they were rapidly coated with a beautiful covering of nickel, in many cases adhering tenaciously, and having a surface resembling Etruscan gold in texture. The nickel, as it is precipitated, would run down the sides of the bars and trickle from their ends, forming little buttons in the bottom of the crucible. These buttons contained considerable quantities of iron, although the iron bars were suspended some distance above them. From this it is to be inferred that the iron alloyed with the freshly

from the comparatively cool surface of contact between the copper and the slag, nickel did rapidly precipitate.

To make this precipitation of metals from their fused slags more thorough and rapid, we propose to pass a current of electricity through the slag while it lies melted on the hearth of a reverberatory, or other suitable furnace. The furnace bottom would be made the anode of the current, and the metallic bars inserted into the fused slag would act as cathodes. In many furnaces the bottom contains sufficient metallic matter to make a very efficient cathode, but a carbon bottom, such as has been used for the production of ferromanganese on the open hearth, would probably act much more efficiently.

The writers hope at another time to present to you further facts as to the relative positions of the metals on the scale of electropositeness at these high temperatures, and in slags of different compositions and different degrees of acidity.

BEVERIDGE DISTRICT.—The new five-stamp

WOOD GRASS.—*Muhlenbergia Mexicana*.

precipitated or nascent nickel while the latter was running down its sides. Whether it would be possible to precipitate nickel at so low a temperature that iron would not alloy with it, we cannot state; but that nickel is precipitated from its slags at temperatures considerably below its melting point is indicated by the following experiment: When copper bars were inserted in a metal nickel-bearing slag, the sides of the bars were rapidly coated with metallic nickel. Now, at the point of contact of the slag with the copper bars, the slag can have been but slightly above the melting point of copper, and therefore far below that of nickel; for the solid part of the copper bars cannot have been hotter than the melting point of copper. The melted layer of copper (if any) on the surface of the solid portion must have been very thin, as otherwise it would have trickled down the sides of the solid portion, and, being very thin, its outside surface can have been but little above the surface of the solid portion, which latter could not have been hotter than the melting point of copper; and, finally, the layer of slag which was in contact with the thin film of copper on the outside of the copper bars must have been but infinitesimally hotter than the surface of that melted copper. Nevertheless,

mill is being pushed to completion as fast as possible by Mr. L. Lasky, the owner. It is intended to have the mill in running order by March 15th, when crushing will be immediately commenced on ore from the Keynot and other mines contiguous to the mill. Rich quartz is now being extracted from a number of claims, and there is every prospect that plenty of ore will be produced to keep the mill in constant operation. Over \$350,000 in gold has already been taken out in the past two years, and that mostly from the Keynot mine alone, which has large quantities of ore yet in sight, but some dead work will have to be done before any considerable quantity of ore can be taken out. Several other promising claims in this district have not yet been worked to any considerable extent, but some of them promise to yield largely when opened. Beveridge will be a busy camp during the coming summer.—*Inyo Independent*.

A BILL has been introduced into the Legislature requiring articles manufactured in the reformatory institutions or prisons of Pennsylvania to be distinctly branded and marked as articles of convict labor before being placed on the markets.

A Grass for Low Ground.

A grass for low moist land is sometimes wanted even in a dry State like California, and in suitable situations, perhaps, the grass shown on this page may be worthy of a trial. It is *Muhlenbergia Mexicana*, or "wood grass." It is a perennial grass of rather decumbent habit, two to three feet high, very much branched from scaly, creeping root stocks. The culm has numerous short joints below, which are frequently bent, and rooting near the base, and sending out many long, slender, leafy, lateral branches, which give rise from the joints and at the apex to the flowering panicles, which are sometimes partially included in the leaf sheaths. The leaves are three to four inches long, and two to three lines wide, gradually pointed. The panicles are narrow, usually two or three inches long, and composed of 5 to 10 spike-like branches, closely approximated or becoming distant and interrupted below. The spikelets are single-flowered, consisting of a pair of outer empty glumes, which are abruptly sharp-pointed, and nearly as long as the flowering glume, which is narrow, strongly three-nerved and acute, with usually a few soft hairs at the base and on the nerves. The palea is of equal length, with its glume also acute, but not bristle-pointed.

This grass is frequently found in moist woods and low meadows, or in prairie bogs. It probably would not endure open upland culture, but in its native situation it fills an important part among indigenous grasses.

Professor Killebrew says: It thrives best in bottoms, where it grows freely. It is slower in maturing than most grasses, and hence fills a vacuum caused by the seeding and dying out of the earlier grasses. It is eaten with avidity by cattle, and is a good grass in its place.

Elko County.

Its Mines Officially Reported.

H. V. Mundell who has been Assessor of Elko county for the past four years, furnished in accordance with the law, a report upon the physical and financial condition of the county. That portion of Mr. Mundell's referring to Elko county we give, as follows:

The condition and prospects of the mining interest of Elko county have materially brightened during the past year, and particularly in the Tuscarora Mining District. After the flush times that usually follow the discovery and early development of a new mining region, Tuscarora enjoyed a prosperity proportionally equal to that of any mining district in Nevada. The customary reaction succeeded; cessation of labor underground, closing of some of the principal mills, and a period of general dullness and inactivity; but during the past year a revival has changed much of this depression, and the tendency of things is now upward and onward. Unless some unexpected backset occurs to interrupt this progression, Tuscarora in 1883 will show a certificate of deposit, in the shape of solid silver bricks, that will remind one of its former days. This improvement, commencing last spring, has been steadily strengthened by the developments made during the past summer and fall. The indications are now good for a long period of steadily-increasing and permanent prosperity.

This improvement at Tuscarora has been of material advantage to other portions of Elko county, and incidentally to the State. Tuscarora receives most of its supplies of every sort from the railroad, at the depot at Elko, the county seat. There have not been teams enough at Elko during the fall to keep the depot clear of this northern freight; but fortunately the fall of 1882 was so open and mild that the roads were in condition for use much longer and later than usual. Lumber, coal, salt, grain, and general merchandise of every sort, have been piled up weeks at a time awaiting shipment. This, of course, added to the general value of assessable property in Elko county, increased the poll tax revenue, and has given a permanency to the values of every description, and indirectly increased the revenues of both State and county by a renewed local mercantile activity.

The principal producing mine at Tuscarora during the past two years, as shown by the reports of mining superintendents, has been the Navajo. The Navajo mine, under the management of W. C. Price, superintendents, has done considerable and expensive work, and the result shows the management has been done with good judgment. The Independence, Belle Isle and North Belle Isle, have produced moderately. The Grand Prize, John E. Dixon, superintendent, still makes a very fair showing, though not as great as in the days when it made the reputation of Tuscarora. The product during the past two years shows that this favorite mine is likely to long maintain its prestige. There has been considerable ore handled by outside or independent parties, among whom Whitney, Vesey & Co., Brown & Urton are prominent. The Central Consolidated has also done considerable work in developing its mine.

By vaporizing two quarts of tobacco juice over a slow fire, Baron Rothschild's gardener, at Paris, Monsieur Bozard, destroys all the troublesome insects that may be contained in the hot-house in which the operation is performed. He considers the remedy infallible, and says it rarely injures the tenderest plants,

THE ENGINEER.

USEFUL INFORMATION.

Facts for the Curious.

The greyhound runs by sight only, and this we observe as a fact. The carrier pigeon flies his 250 miles homeward by eyesight—namely, from point to point of objects which he has marked; but this is only our conjecture. The fierce dragon-fly, with 12,000 lenses in his eye, darts from angle to angle with the rapidity of a sword and as rapidly darts back; not turning in the air, but with a dash reversing the action of his four wings, and instantaneously calculating the distance of the objects, or he would dash himself to pieces. But in what conformation of the eye does this consist? No one can answer.

A cloud of 10,000 gnats dance up and down in the sun, the minutest interval between them, yet no one knocks another headlong upon the grass, or breaks a leg or a wing, long and delicate as these are. Suddenly, amidst your admiration of this dance, a peculiar high-shouldered vicious gnat, with long pendant nose, starts out of the rising and falling cloud, and settling on your cheek inserts a poisonous sting. What possessed the little wretch to do this? Did he smell blood in the mazy dance? No one knows.

A carriage comes suddenly upon a flock of geese on a narrow country road, and drives straight through the middle of them. A goose was never yet fairly run over, nor a duck. They are under the very wheels and hoofs, and yet they somehow contrive to flap and waddle off. Habitually stupid, insolent and heavy, they are nevertheless equal to any emergency.

Why does the lonely woodpecker, when he descends his tree and goes to drink, stop several times before he takes his draught? No one knows.

The power of judging of actual danger, and the free and easy boldness which results from it, are by no means uncommon. Many birds seem to have a most correct notion of a gun's range, and while scrupulously careful to keep beyond it, confine their care to this caution; the most obvious resource would be to fly right away out of sight and hearing, which they do not choose to do. And they sometimes appear to make even an ostentatious use of their power, fairly putting their wit and cleverness in antagonism to that of man, for the benefit of their fellows.

We lately read an account, by a naturalist in Brazil, of an expedition he made to one of the islands of the Amazon to shoot spoon-bills, ibises and other of the magnificent grollatorial birds which were most abundant there. His design was completely baffled, however, by a wretched little sandpiper that preceded him, continually uttering his tell-tale cry, which at once aroused all the birds within hearing. All day this individual bird continued his self-imposed duty of sentinel to others, effectually preventing the approach of the fowler to the game, yet managing to keep out of range of his gun.

How to Split a Sheet of Paper.

Many people who have not seen this done might think it impossible; yet it is not only possible, but extremely easy, as was explained in this paper several years ago, and recently described in the *British and Colonial Printer and Stationer*, which is as follows: Get a piece of plate glass, and place on it a sheet of paper; then let the latter be thoroughly soaked. With care and a little dexterity the sheet can be split by the top surface being removed. But the best plan is to paste a piece of cloth or strong paper to each side of the sheet to be split. When dry, violently, and without hesitation, pull the two pieces asunder, when part of the sheet will be found to have adhered to one, and part to the other. Soften the paste in water, and the pieces can be easily removed from the cloth. The process is generally demonstrated as a matter of curiosity, yet it can be utilized in various ways. If we want to paste in a scrap book a newspaper article printed on both sides of the paper, and possess only one copy, it is very convenient to know how to detach the one side from the other. The paper, when split, as may be imagined, is more transparent than it was before being subjected to the operation, and the printing ink somewhat duller; otherwise the two pieces present the appearance of the original, if again brought together. Some time ago, says the *Stationer*, the information of how to do this splitting was advertised to be sold for a considerable sum.

ARTIFICIAL SPICES.—A descendant of the Yankee who is credited with having produced that refinement of invention, the "wooden nutmeg," has, according to the *Madras Mail*, improved upon the example of his predecessor, and produced wooden cloves. That journal records the fact that several bags of cloves lately received in London from Zanzibar were found on arrival to contain artificial cloves neatly manufactured by machinery. They were made of soft deal, stained of a dark color, and soaked in a solution of essence of cloves to give them the requisite spicy odor. It is further added, that they were traced as having been imported from America into Zanzibar.

AN EXPERIMENT WITH SALT.—Do you want to grow salt, and, at the same time, have an interesting, handsome ornament? The proceeding is a novel chemical experiment that may be tried by any one. Put in a goblet one tablespoonful of salt and one tablespoonful of bluing; fill the goblet two thirds full of water and set in a position where it will have plenty of warmth and sunlight. In a little while sparkling crystals will commence forming on the outside of the glass, and it is both a novel and interesting sight to watch it gradually growing day by day, until the outside of the goblet is entirely covered over with beautiful white crystals. Another variation of this beautiful experiment would be to take a goblet with the base broken off and fasten it in the center of a thin piece of board, which may be round, square or oblong. After the crystals have formed on the glass, set it on a tiny wall bracket, and place a bright holiday or birthday card in front of it; this will hide the base, on which no crystals will form. After this is done, fill the goblet with flowers or dried grasses, and you will have a vase which will cost comparatively little, and in reality adds to the l'rie-a-brac of the room.

A NEW METHOD OF SILVERING MIRRORS. According to an exchange, the addition of glycerol to an ammoniacal solution of nitrate of silver produces a brown color, accompanied by a slowly-forming deposit of a black substance. The action is greatly accelerated by the application of heat, and a portion of the silver is deposited as a steel-gray mirror. If a few drops of potash solution are added to the mixture of glycerol and ammoniacal silver, a brilliant mirror is soon formed on the interior of the vessel. The phenomenon is even more striking if the ammoniacal silver solution be first mixed with potash, and glycerol then added; directly the glycerol comes in contact with the silver solution, reduction takes place with formation of a brilliant metallic mirror. If ether is added to the mixture of glycerol, potash and ammoniacal silver nitrate as soon as it touches the aqueous liquid, a metallic ring is formed at the junction of the two liquids, and in a few seconds reduction is complete through the whole bulk of liquid. If alcohol is added to the glycerol-silver mixture, reduction is somewhat accelerated and the metallic mirror is always brilliant. The results of these experiments show that the reducing action of glycerol on silver salts may be applied technically with advantage to silvering mirrors, both from the facility with which the process may be conducted and from its economy.

DANGEROUS BILLIARD BALLS.—In Heidelberg the other day, says an exchange, a man was holding a lighted cigar and a celluloid billiard ball in the same hand, and the two coming in contact, the outer shell of the ball exploded. He burned his hand a little before he was able to drop the ball.

GOOD HEALTH.

Fruit Juices.

There is often a decided objection to the use of our coarsest fruits, especially in sickness, or when the stomach or bowels may be in a sensitive state, on account of the irritation of the angular and sharp seeds, and peel or skin. Like the hull of the wheat—or hulls, as there are five different layers, which should be removed, in most if not all cases, from the flour—these seeds and rinds are often sources of irritation to the sensitive coats of the stomach, causing many forms of disease, particularly in the hot weather. It is exceedingly fortunate that these juices do not require digestion like the solids; but, like water, enter the system unchanged, there to be assimilated, of course, affording nutrition, with no use of the digestive apparatus, or but slight effort, that of absorption. (If desirable these juices may be prepared at this season, thoroughly scalded, canned like fruit, kept from the air and in a cool place, and used in the following spring, when such are exceedingly valuable, especially for those having debilitated digestion.)

It is very plain that if they demand no digestion, still containing all of the nourishment of the berry, securing rest for the stomach, the dyspeptic, etc., may well use this juice as a substitute for solids, for such a part of the time as will allow rest, time for the digestive organs to recuperate and become sufficiently strong to perform their usual amount of labor.

I will here remark that their use all the time, instead of at the last meal, or when the appetite may be particularly imperfect, would tend to debilitate the stomach, since, like all unused organs, the time would come when it would lose the power of action. As a general principle, the substitution of these for solids for one or two meals at most, using the simplest form of solids, as the raw egg or boiled rice, would be as much as would be advisable, save in extreme cases, when such nourishment for a week or less would be a choice of evils.

Milk should not be regarded as of this class, since it is solidified before digestion. It is not a proper drink between meals, since it requires digestion like solids. When there is much feverishness, with some appetite, the more acid juices, like that of the strawberry or the currant, may prove of great value without sugar, for that is a "heater." These tend to reduce

feverishness, though, if too acid, they may irritate the stomach, producing the canker.

The fresh juice of an apple—not fermented juice, or cider—is very appropriate and useful, the apple containing more nourishment than the potato. These juices may be used with great propriety when the appetite seems waning, or when but little food is indicated, for nourishment is obtained without labor.—*Golden Rule.*

Fat and Lean.

A little reflection will enable one to see that as the causes of these opposite conditions are as unlike as possible, so must be the treatment. To reduce flesh we have simply to reduce the quantity and quality of the food consumed, and when this is done judiciously, the general health of the patient is more likely to be improved than impaired. But were a lean man to attempt to increase his weight by gorging himself with rich food, he would soon find his object defeated, and himself a dyspeptic, and more emaciated than ever. We cannot force the body to receive and assimilate more food than it requires; but there is often a way to increase its requirements, and be thus safely increased the weight of the body, and the general health. A serious obstacle has frequently to be encountered from the fact that lean persons are usually nervous and restless; and these are conditions unfavorable to increase of flesh. This is true of all animals; when it is desired to fatten an animal his range is confined to narrow limits; the food given him is nutritious rather than bulky; he has comfortable quarters, and sleep and quiet are encouraged. Men are animals, and the same general rules, for the same purpose will apply to them, provided the general health is good. Lazy persons are seldom thin. If, however, emaciation depends on ill health, a different treatment is required. Instead of quiet the patient must have regular exercise in the open air; horse-back riding if possible, and whatever else that promises improvement of the general health; when emaciation is the result of disease of the lungs, if not too far advanced, this treatment, steadily pursued, often results in permanent cure. Indeed many physicians can refer to persons thus restored to health, who were at one time supposed to be incurable. It has been claimed—and it is probably true—that fresh rich milk is the best of all foods for producing fat. It is true that if a person who is inclined to be fleshy eats bread and milk regularly every day, and particularly in the evening, he will soon assume Aldermanic proportions. Milk is the natural food of man. It is nutritious, and not so liable as other foods to impair digestion.

Sometimes one's mental condition has more to do with bodily health than anything else. As a rule, fat persons are jolly and laughter-loving. Lean people are more often fretful, and have their eyes too steadily fixed on the dark side of every problem. If possible cease to fret and strive to "laugh and grow fat."

CANNED POISON.—Canned fruits, vegetables, meats, fish, soup, even canned puddings, says the *New York Herald*, are now not uncommon articles of diet, and we believe the introduction of these alimentary substances has been, upon the whole, a great benefit to the people; for fruit, vegetables and meat even, that at one season of the year would go to waste through the plenty that made them superfluous, are by the canning system economized for use in other seasons. But it is certain that several articles now put in tins should be put up in glass or earthenware to make them safe articles of diet. All substances that contain acids capable of attacking the solder or tin of the cans combine with these metals to make poisonous compounds, and may cause illness and even death.

ANTISEPTIC PROPERTIES OF PEAT.—Dr. Neuber, at a late Congress of German Surgeons, spoke highly of the antiseptic virtue of peat, or black earth, which is filled into bags made of loose gauze and laid over wounds. The bags are held in place by bandages of the same material. There seems to be little or no necessity to change the dressing. All secretions are rapidly absorbed by the earth or turf, and the healing proceeds very rapidly.

SMALL-POX seems to be getting the upper hand of the authorities at Leadville. Public schools are closed, a new pest house is being built, and the alarm is becoming general, and also reaching out into the surrounding towns. Some of them are establishing quarantine. The Denver authorities are using every precaution to prevent its appearance there, and have been successful thus far.

A MAN near Anaheim was taken very ill, and desired an allopathic physician. Though he was in his own house, a family living with him preferred a homeopathic, and when the old-school doctor arrived they drove him away with threats. He appealed to the Court for redress, and the Judge decided that a sick man has an inalienable right to select the physician he prefers.

EARACHE.—The treatment of earache depends entirely upon its cause. It may be due to functional trouble, like indigestion, liver derangement, splenic disorder, etc. It may be due to nervous disease. When chronic, good medical advice should be sought. The ear is too delicate and a too important organ to be neglected or trifled with.

THE GREAT BRIDGE OF INDIA. It is thought that of all the bridges in India the Attock bridge, when completed, will stand second to none. It will consist of five spans, two of 308 feet each, and three of 257 feet each, and will be entirely of iron. The material for the spans and for the piers was made and shipped by English firms. The third pier that stands in the middle of the river, and is exposed to all the violence of floods; will be protected by a massive cutwater about 100 feet high. It has also been proposed to protect the remaining piers by cutwaters, recent floods having shown the advisability of such a course. The bridge is reported to be making rapid progress toward completion, and it is thought that at the latest another year will see it in working order. The ironwork of the first two spans is now completed, and the staging for the third and fifth spans is progressing favorably.

THE RESPONSIBILITIES OF AN ENGINEER.—An engineer who tries to understand his business must study much; he must be above the common laborer or mill operative, and in fact above the head bookkeeper and confidential clerk in point of education,—he must have a clear head, a steady hand, and a brave heart, they have nothing strange or new to contend with; their paths are well beaten and plain; but with the engineer, how is it? He has that subtle thing, fire, that powerful agent steam, to handle and control, and out of his own brains he must find many of their laws. Thence the emergencies that arise every day and the responsibility which he carries; he is his brother's keeper; he, by a very small mistake, may hurl hundreds into suffering and death,—and he must contend with all these subtle agencies and bear these awful responsibilities, and should be paid accordingly.

A SUCCESSFUL ENGINEERING FEAT.—A difficult feat of engineering was recently accomplished on the Pittsburgh and Western railroad. Several places along the line required the stoppage of trains before they could be adjusted to broad-gauge. One of these points was the Summit tunnel. Its bed was lowered nine feet without stopping a train. The work was accomplished by the excavation of the bed of the tunnel while the track was kept up by trestle-work. A row of blasts would be fixed ready for firing, and as soon as a train had passed through they would be touched off and the debris cleared up before the next train arrived. The track for the broad-gauge was laid nine feet below the narrow-gauge, and on Sunday cars were run in on the lower tracks and the trestle for the narrow-gauge knocked down and dragged out.

ANOTHER IMPORTANT CANAL.—There seems to be just now a general movement "all along the line" in the way of changing the face of nature for the more convenient arrangement of water ways for commercial traffic. The latest proposition is nothing less than the separation of England and Scotland by a waterway from the Solway Firth to the River Tyne. An engineer is at present working on the surveys, and estimates are promised for early publication. This canal would have a length of only 80 miles, or 20 miles less than the Suez. It would, of course, afford a very convenient short cut across the country for ocean steamers. Some 40 years ago a scheme of the same kind was talked of.

REMOVING SAND FROM RIVERS.—An engineer in Oregon has put into practical operation a plan recently proposed for removing sand from rivers. According to the *Inter-Ocean* he removed 22,000 cubic yards at a cost of \$1,000, while by dredging the cost would have been \$10,000. The process is to load a steamer by the stern, anchor her head up stream, and then let her turn her propeller. This loosens the sand, which is carried away by the current. A steamer in that way deepened the channel of the Columbia river 18 feet, by a width of 75 feet, in 20 minutes.

ANOTHER TUNNEL UNDER THE HUDSON is projected at New York, the tunnel to be used for railroad purposes and to be connected on the New York side with the proposed central underground railway, from the vicinity of the City Hall up to the Hudson railroad, at Fifty-fifth street. This tunnel will be double tracked and have a capacity for moving 5,000 passenger cars daily. The projectors evidently mean business.

A CHINESE BRIDGE.—China is ahead on bridges; the largest in the world being her structure at Lagang, over an arm of the China sea. It is five miles long, built entirely of stone, has 300 arches 70 feet high and a roadway 70 feet wide. The parapet is a balustrade, and each of the pillars, which are 75 feet apart, supports a pedestal on which is placed a lion, 21 feet long, made of one block of marble.

UNDERGROUND WIRES IN CHICAGO.—After the 1st of May, in Chicago, no person or corporation will be permitted to maintain or use any telegraph pole, telegraph wire or electric conductor in any street or alley of that city. Every great fire adds new emphasis to the cry of "Put the wires underground."

Passing Events.

Very little news of an important nature comes to us from the mining regions. Occasional "strikes" are recorded in mines that are being developed, but at this season of the year there is not much general prospecting being done. Within the next month, however, the prospectors will begin to stir out of their winter quarters and roam the hills again.

News comes of heavy storms on the Atlantic coast, but thus far fine weather seems to be the rule in California. A good heavy rain storm would be heartily welcome everywhere. It is feared now that the water season for the miners will be very light indeed, as there is such a small storage of snow in the mountains, and the farmers have been for some time complaining of the dry season.

From present appearances, our northern regions will receive more attention the coming season than ever before. Idaho, Montana and Alaska are each being looked to as new territory by many prospectors. The latter, in particular, perhaps because it is furthest off, seems to possess many attractions to the nomadic miner, who is always looking for better diggings.

In the cases of the North Noonday Mining Co., the Noonday Mining Co., and the Red Cloud Con. Mining Co., insolvent debtors, Irwin C. Stump has been appointed assignee, with bonds fixed at \$10,000 in each case.

Copper.

The consumption of copper is steadily increasing, as is also the production. The opening of the new copper fields in Arizona, New Mexico, Colorado, and Montana is gradually having its influence, and in some parts of our mining regions more attention is being paid to copper than anything else. Of course, our production on this coast is small, as compared with the Michigan copper mines, which have been worked for years, but the number of mines and of active furnaces is rapidly multiplying. The English market for copper, to a certain extent, regulates that of the world. While the increase of productions was 10,000 tons last year, the English home consumption increased 12,000 tons over 1881. The value of the steam engines and machinery exported from England was £11,962,660, against £9,960,206 in 1881, which at once accounts for a considerable portion of the large home consumption. The French consumption of copper last year was 5,700 tons less than in 1881, owing to the unsatisfactory state of financial affairs in that country. The decrease of exports of English copper was made up by a diminution of 3,000 tons to Germany and Holland, 850 tons to Russia, 750 tons to Egypt, 1,000 tons to France and 1,000 tons to the other countries. India took 1,000 tons more than in 1881. The total exports from England and consumption in England and France, although only 1,000 tons more in 1882 than in 1881, was 19,000 tons greater in these two years than the two previous years. The total English imports of copper in 1882 amounted to 95,222 tons. The average price of English precipitate was, in 1882, 13s. 10½d.

A short time since we stated that it was understood that about 5,000 tons of Lake Superior copper had been sold by contract at 18 cents per pound, with a guarantee on the part of the sellers against lower prices being accepted for exports to Europe when stocks increase or the necessity for keeping prices against the home consumers require it. This would seem to point to the expectation on the part of the Lake Superior companies that any exports to Europe of their surplus stock will not be required for some time to come. This coast is now being considered in the copper market more than ever before, and it will be still more so as the new mines are opened.

Latest English quotations are: Good ordinary brands of Chili bars, £64 15s. to £65; ore, 13s. 1½d., and regulus, 13s. 4½d. per unit. The total visible supply of copper in Liverpool on Feb. 1st, according to James Lewis & Co.'s ore and metal report was, 49,823 tons fine against 49,876 tons on Jan. 1st.

The import of Spanish precipitate and copper produce from all countries, except Chili, into Liverpool and Swansea in 1882 was 24,459. The import of Australia, etc., copper into London was 9,735 tons fine. The import of Chili ore, regulus, bars and ingots into England was 30,112 tons fine. The import of Spanish pyrites into England was 15,673 tons fine. The total import of copper produce into England (exclusive of Glasgow and Newcastle) was 79,979 tons fine. The import of American copper into France was 1,379 tons fine. The import of Chili copper into France was 12,194 tons fine. The total import of copper produce into France was 13,573 tons fine. The total import of copper produce into England and France was 93,553 tons fine. The export from Chili to all countries is estimated at 42,000 tons fine.

The following additional statistics of copper are instructive: Imports into England in 1882, 95,222 tons, fine; exports from England, 53,684 tons; British production, 2,599 tons; English home consumption, 44,820 tons; imports of all kinds into France direct, 13,573 tons; export of English copper to France, 7,022; French consumption of copper, imported direct, 14,506 tons; French consumption of English copper and copper imported direct, 21,528 tons; English consumption and French consumption of copper, imported direct and from England, 66,340; English consumption, English exports, and French consumption of copper imported direct, 115,010 tons.

At the annual meeting of the Sutro Tunnel company, there were represented 1,050,000 out of 2,000,000 shares. The following were elected Trustees for the ensuing year: C. W. Brush, W. Johns, F. F. Low, David Cahn, Thomas P. Storey, Hugh Marshall and P. W. Ames.

New Portable Assay Furnace.

John C. Tappeiner of Bisbee, Cochise Co., Arizona, has just patented, through the MINING AND SCIENTIFIC PRESS PATENT AGENCY, an assay furnace which is intended for the use of prospectors and miners, and to be easily packed up and carried from place to place, as needed. At the top it is decreased in size, and has a collar, upon which the lower section of the pipe is made to fit. The pipe is made tapering, decreasing in size toward the top, and in sections which may be telescoped together, so that the whole can be reversed and placed in the furnace above the grate. A cap then closes the whole and is retained in place by a hinge-clamp on a lock wheel, which also serves to retain the pipe in place when in use.

The exterior casing of the body of the furnace is made of metal or suitable material, and the interior lined with fire-brick, clay, or any non-conducting, heat-resisting material. The body is made tapering, from four to 10 inches in diameter, and about three times as high, increasing in size from the bottom to the shoulders at the top, so that it has the greatest diameter where the greatest amount of room is required. This also gives a better draft. The shoulders of the cover are curved inward from the point of greatest diameter, and a collar is formed at the top to receive the pipe. Within the furnace and around the upper edge is an iron ring about one inch wide and a quarter of an inch thick. This ring resists external pressure, and prevents the furnace being crushed when it is packed on an animal for transportation.

The fire grate is preferably made of sheet iron, coated also with fire clay and with round holes punched in it. The burrs formed by punching the holes are turned up, and assist in holding the coating of fire-clay in place, the holes passing through the clay above. Below the grate is a draft-regulating door, and there is a door about three quarters of an inch above the grate for the introduction of rock drills, etc., to heat them for tempering, when desired. Above this is another door of the proper shape to receive a muffle which fits it, and may be introduced whenever needed.

Sections of pipe are made tapering so that the lower end of the lower section will fit over the collar at the top of the furnace, and the lower end of each succeeding joint fits tightly into the top of the next lower one, when they are all drawn out, thus making a pipe of any desired length.

A door is made in the lowest section of the pipe, through which fuel is supplied to the furnace from time to time, as needed, and through which the crucibles may be introduced.

In order to hold the cover in place and steady it and the pipe, a clamp is employed which surrounds its collar. One end extends down upon the side of the furnace, and has a hinge joint at the other end extending down upon the opposite side of the furnace, and has a lock or pin to hold it.

When the furnace is to be transported, or is not in use, the pipe is taken off, and by reversing it and pressing its small end upon the ground the joints will be loosened where the end of one section binds on the next, and they may be telescoped. When the pipes are telescoped they are put in the furnace small end down, and occupy the space between the grate and the top. Three pair of assay tongs will fit between the pipe and inside of the furnace.

The flux boxes are made round, about two inches high, with central partitions and hinges so that each will form two boxes, and they will fit loosely inside the pipe. The iron muffle will also fit inside the pipe, and will be in no danger of breakage during transportation.

When the whole is in place the cover is shut down upon the top, and is secured by the clamp, the whole being then ready for transportation.

This apparatus is designed for the use of assayers, miners or prospectors, and is compact and portable. It can be packed upon an animal over any trail and into districts, where it can be made available in determining the ore values upon the spot. It is also useful for sharpening and tempering picks, drills and other tools.

At the California State Prison, the following is the result of jute manufacture: Net profits from the manufacture of jute for the month of August, \$6,000; twelve months, \$72,000; net profits from other manufactures, \$65,000; total, \$137,000; total prison disbursements for the year, \$159,831; excess of expenditures over profits of manufactures, \$22,831. The last amount represents the sum which the State will have to pay, and for two years it would amount to \$45,831.

The Mining Bureau.

In conversation with the State Mineralogist one day this week, he stated that he did not see how he would be able to keep the State Museum open unless more funds were forthcoming for its maintenance. On inquiry at the office of the License Collector, the fact is developed that the fund derived from the tax on transfer of mining stock, upon which the Bureau is supported, will amount, for the next quarter, to only \$1,216. The salary of the State Mineralogist is \$250 per month, and the rent is \$200, these two items alone more than consuming the income, leaving nothing for Secretary, janitor, stamps, or any of the ordinary expenses of a museum. The collection is very rapidly increasing, and certain expenses are entailed in arranging the specimens and carrying on the exchange system. More cases, are needed, also. In fact, all the specimens which have come in for some time have been packed up and put away, because there were no means for displaying them.

A bill has passed the Senate appropriating, in addition to the irregular income from the source noted, and on which the Bureau has entirely depended, the sum of \$10,000 for two years, or \$5,000 per year. But Mr. Hanks says that this is not enough to carry on the institution properly, and even with this appropriation he will be compelled to close the Museum and give up that part of the Bureau's functions. It will be necessary to box up and store the collection. Then Mr. Hanks will take a small office and attend to the affairs of the Bureau without having any collection exhibited at all.

It seems too bad, just at a time when we are to have a large influx of visitors from the East, that our collection of minerals must be closed up. If, however, proper provision cannot be made to keep it up in good shape, it is just as well that this museum be closed, and the Bureau be one of information only, without a museum.

The collection of ores and minerals can then be turned over to some other State institution, the University for instance, as it is the property of the State. It is, of course, desirable to have it maintained here, but, that being impossible, it will be more useful at the University than elsewhere, since it will swell materially the already large collection at that institution and be available to all who desire to go to Berkeley to examine it.

It is to be hoped, however, that with the tax income and the appropriation, Mr. Hanks will find some way of keeping the museum open for the next two years, by which time it may be that more interest will be shown by California in its mining industry, and this representative institution be properly supported.

Mining Debris Dams.

Last year a temporary injunction was issued at the suit of Diggorry Hobbs against the Sacramento and Amador Canal Co., a hydraulic mining company operating at Hilltop, on the Cosumnes river, near Michigan Bar. The company afterwards constructed dams to impound the debris. At the hearing before Judge McFarland, of Sacramento, recently, plaintiff claimed that these dams were not dams at all, and backed his allegation with large photographic views, showing a structure something like a dam, with an open cut or flume in the center, through which, it was asserted, all kinds of material was carried by the water. The plaintiff or his attorney did not seem to understand how such dams are made, when built properly, and they thought when the photographs were made they had a sure thing on showing purposely careless construction. It is, of course, necessary, while retaining the debris, to allow the water to pass over. As the debris packs up behind the dam, and gradually rises, the dam is gradually raised in the center. The wisacres who brought in those photographs did not know of the necessity of thus gradually building the dam up. They evidently supposed it necessary to build the dam to its full height right off, and have a 100-foot dam for a foot of tailings, holding back 99 feet of water to do this. The miners think this is a pretty good joke on their rivals, the farmers, as they say most farmers consider themselves just as good engineers as those in the profession.

At all events, when Judge McFarland last Monday decided the case, he did not accept the position of plaintiff, that the defendant had no right to pollute the waters of the stream at all, but he modified the injunction, allowing the defendant to work its mines, on condition of exercising the greatest diligence in keeping its dams up to their present efficiency. This, he held to be in accordance with the decision in the Gold Run case.

Anderson's Stock Car.

Very great attention is now being paid to the question of the proper transportation of live stock by railroad. Efforts are being made to cure existing evils, as far as possible, by providing better means of caring for the live stock in transit. A great deal of thought and study is being extended in this direction in the East, as well as here. Mr. Adolph V. Anderson, of Virginia City, Nevada, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency an improved stock car, which is intended to facilitate the transportation of cattle, horses and other animals in safety and comfort.

Such are the various improvements in construction that it will be necessary to go somewhat into detail in order to describe the invention. Six views are given in the accompanying engraving. Fig. 1 is a sectional side elevation of a car to which the improvements have been applied, parts being broken away. Fig. 2 is a sectional side elevation of a water-trough and its supports. Fig. 3 is a plan view of a feed trough, folded. Fig. 4 is a sectional end elevation of the same, opened. Fig. 5 is a plan view, partly in section, of a part of the car. Fig. 6 is a sectional end elevation of the same.

A represents an ordinary box-car, the interior of which is divided into a number of stalls by partitions. Each stall partition is formed of three upright boards or bars, B, C, D, which are connected by two pairs of bars, E, F. The outer ends of the bars, E, F, are hinged by bolts, or other suitable means, to the outer bars, B, D. The inner ends of the bars, E, F, are hinged to each other by suitable means, which bolts pass through a longitudinal slot in the central bar, C, and are attached to the ends of connecting bars, G, placed upon the sides of the said central upright, so that the three uprights, B, C, D, can be drawn together and forced apart to contract and expand the partition by operating the bars, E, J.

The outer, or forward end of the lower bar, F, is extended beyond its pivot, and to the extended end is pivoted the upper end of a short link, H, the lower end of which is pivoted to a collar, I, attached to an upright rod, J. The rod, J, slides up and down in keepers attached to the car body, passes through a guide hole in the bottom of the car, and to its lower end is hinged a lever, K, which is fulcrumed to a support attached to the car frame, so that the stall partition can be contracted and expanded from outside the car by operating the lever, K.

The outer edge of the upright, D, is hinged to the car body, so that the partition, when contracted, can be swung around against the side of the car, so as to be out of the way when freight is to be stowed in the car. The upper and lower ends of the uprights, B, C, slide in grooves in the guide bar, L, the outer ends of which are rigidly attached to the ends of the upright, D.

The guide-bars, L, are made in two parts, hinged to each other at the outer edge of the partition when contracted, so that the hinged parts of the bars can be folded against the edge of the upright, B, when the partition is to be swung against the side of the car. The lower bar, L, is held against lateral movement when in place, by pins, M, inserted upon the opposite sides of the said lower bar, L, near the end of the hinged part of the bar, in holes in a plate, N, let into and secured to the floor of the car. The hinged part of the lower bar, L, is held from lateral movement by two pins, O, hinged to a slotted plate, P, let into and secured to the car floor, so that the pins, O, can be turned up at the opposite sides of the said part of the bar, L, and can be turned down into the slots in the plate, P, when not required for use. The upper bar, L, is held from lateral movement at one side by a bar, Q, attached to the upper part of the car frame, and at the other side by a catch, R, that slides in a guide attached to the top frame of the car, in such a position that the catch, R, will engage with the main part of the bar, L, near its hinged part. The hinged part of the upper bar, L, is held against the stop-bar, Q, by a stationary catch, S, attached to the top frame of the car. The hinged part of the upper bar, L, is supported, when raised into a horizontal position, by a pin, T, inserted in a hole in the stationary catch, S, and in the hinged part of the bar L.

The animal in a stall is kept from backing into an adjacent stall by a bar, U, the inner end of which is slotted to receive the edge of the upright B, to which is attached a pin, V, or other stop to prevent the bar, U, from dropping down too far. The outer end of the bar U, is hinged to a post of the car frame, so that it can be turned up against the said post to allow the animals to pass and when not required for use. When the hinged bar, U, is in an upright position it rests against the side of a guide plate, W, attached to the post of the car frame, and is secured in place by a pin, X, passing through the said plate W, and into the said bar U. The spaces between the rafters of

the car are inclosed to form chambers, Y, to receive grain or other suitable feed, which is inserted through openings Z, in the roof of the car, the said openings being closed by suitable covers, a. With the lower part of each chamber Y, or with a chute, b, connected with the lower part, is connected the upper end of a tube, c, the lower end of which is inserted in the feed-box d, so as to deliver grain into said feed-box as fast as it is eaten out.

Upon one end of each side, l, of the feed-box

the lower bars, E, F, by the bolt that pivots the said bars, E, F, to each other. With this construction the bottom of the feed-box, d, will be raised by the movement of the bars, E, F, in contracting the partition, and the said feed-box will be folded together by the pressure against it of the partition as the said partition is swung around against the side of the car.

To the lower parts of the tubes, c, are attached hands, g, provided with eyes to receive hooks, g', attached to the upper part of the car

out of the way of the animals when passing into and out of the car. When the hinged tube, c, is swung up to the top of the car the discharge opening of the feed-chamber, Y, is closed by a slide, h, which slides in the keepers or guides, i, attached to the upper part of the car.

To each end of the car is attached a water-tank, j, which is made of galvanized sheet-iron, or other suitable material, and with the top of which is connected the end of a tube, k, which extends along the upper part of the car roof, and with it is connected a funnel, l, passing in through the said roof, as shown in Figs. 1 and 6.

With the upper part of each tank, j, is connected the end of a flexible pipe, m, which is provided with a valve, n, at its inner end, and is made of such a length that it can be coupled with the end of a corresponding pipe connected with the adjacent car. With this construction the tanks of all the cars can be filled with water introduced into the funnel, l, of one car, from the station-pipes that supply the engine tank with water, or from any other convenient source.

With the lower part of each tank, j, is connected the end of a pipe, o, which passes along the side of the car to the doorway, and is provided with a series of faucets, p, arranged to discharge water into the various water troughs, q, of the car. Each water trough, q, is provided with hooks, r, which are hooked upon the upper edge of a plate, s, sliding up and down in guides t, attached to the car, and the downward movement of which is limited by a flange, u, or other stop, formed upon or connected with the lower ends of the guides, t.

To the upper end of the supporting slide, s, is attached the lower end of a connecting rod, v, the upper end of which is pivoted to the end of a lever, w. The other end of the lever, w, is pivoted to the car frame. To the lever, w, is pivoted the end of the valve-stem of the faucet, p, and to the said lever is attached the lower end of a spiral or other shaped spring, x, the upper end of which is attached to the car frame. The spring, x, is arranged to hold the faucet, p, open, and is made of such a tension as to support the water trough q, until it is nearly filled with water.

With this construction, when the weight of the water trough, q, and the water contained in it becomes greater than can be sustained by the tension of the spring, x, the said spring yields and allows the trough, q, and the slide, s, to descend, closing the faucet, p, and preventing any more water from flowing out of the said faucet until so much water has been removed from the said trough that it will be raised by the tension of the spring x. This movement opens the faucet, p, and allows the water to again flow into the trough, q, until the descent of the trough again closes the faucet, so that the trough, q, will be constantly supplied with water.

In loading the car with animals the stalls are filled in succession, beginning at the ends of the car, and as each stall is filled the partition separating the stall from the next empty stall is expanded and secured, and the bar, U, is lowered. The double stall at the center of the car is filled last by driving two animals into it.

In unloading the car the animals in the double stall are first driven out, and then the hinged bars, U, are raised, and the partitions are contracted and swung around against the side of the car, from the center toward the ends, in succession. The car can then be washed out with the water remaining in the tanks, and the car is ready to be again loaded with animals or other freight.

This patent is for sale, or royalty rights will be granted. Parties desiring other information may communicate with the inventor at 92, corner B and Mill streets, Virginia, Nev.

A SAFETY BELT MONITOR.—Mr. R. P. Ashley, of Camden, N. J., has recently introduced a very useful and handy device for placing belts on overhead-pulleys, without danger or inconvenience. It consists of a rotating circular plate furnished with a central projecting wrought iron pin—the whole rotating freely at the end of a socketed shaft, fixed to a pole of any desirable length. The pin is introduced under the advancing side of the belt, and the belt lifted by the pin and pressed sideways by the rotating flange, so that it is run directly on the running pulley invariably at the first trial. The device is described as one of those ready things calculated to do away with much inconvenience and many accidents.

THE Albion mine has been placed under the direction of Mr. Reed, for many years Superintendent of the Enreka Con.; a mining man who is competent and reliable.

THE Richmond Con. Mining Co., of Nevada, paid a quarterly dividend of \$2.50 per share, or \$135,000, at London, on the 7th of February, making a total of \$3,909,500 to date.

THE Peabody mine, in Arizona, is reported to be sold to a Scotch company for \$300,000.

SECTIONAL SIDE ELEVATION OF ANDERSON'S PATENT STOCK CAR.

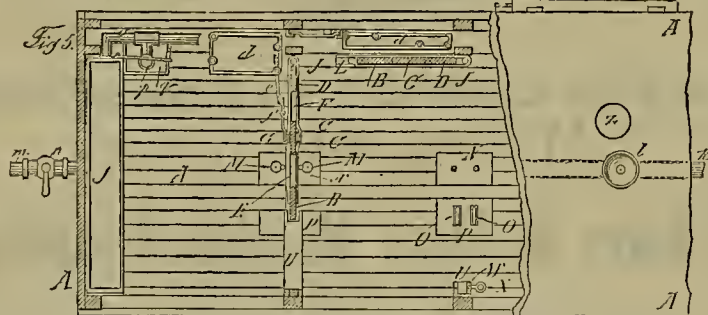

d, at the opposite ends of the said feed-box, is formed a narrow flange, 2, projecting at right angles, to the end of which is hinged the edge of the end piece, 3, the other edge of which is hinged to the end of the other side, 1.

To the lower edge of the inner side, 1, of the feed-box d, is hinged the edge of the bottom, 4,

frame, to support the tubes, c, out of the way and prevent the feed from flowing out of the chambers, Y, when the feed-box, d, is folded or otherwise not in use.

The space opposite the car doors is made to serve as a double stall to receive two animals.

In this case the folding feed-box, d, is attach-

PLAN AND END ELEVATION OF ANDERSON'S STOCK CAR.

the free edge of which, when the said feed-box is opened, rests upon a flange, 5, formed upon or attached to the lower edge of the other side, 1, of the said feed-box.

To the bottom, 4, is rigidly attached a downwardly-projecting arm, e, the lower end of which is pivoted to the outer end of a connecting bar, f, the inner end of which is pivoted to

the inner side of the car door, and the feed-discharge tube, c, is hinged at its upper end to the top of the car frame in such a position that its open upper end will cover the discharge opening of the feed-chamber. The hinging of the tube, c, allows the said tube to be swung up close to the roof of the car, and hung upon its supporting hook, so as to be entirely

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Buillon and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trunnels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanics in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lb. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

WEEK ENDING FEB. 27, 1883.

273,021.—ROLLER DREDGER.—A. J. Burt, Olympia, W. T.

273,092.—AUTOMATIC TIME GLOBE.—Andrew Jackson, S. F.

273,095.—TAIL PIECE AND REIN PROTECTOR FOR HARNESSES.—C. H. Mead, Jr., S. F.

273,109.—COOKING CABINET.—Adolph Segal, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC TIME GLOBE.—Andrew Jackson, No. 273,092. Dated February 27, 1883. The inventor calls this an "Improved Astronomical and Geographical Automatic Time Chart and Globe." It consists in a peculiar terrestrial globe, upon the base of which is marked distinct series of lines representing a general calendar, as the various divisions of time, the position and movement of the sun, and its effect upon the length of day and difference between the mean and sun time, and others of like nature, while the top is provided with a revolving cap upon which is marked the divisions of hours up to 24, to make the day. The interior of the globe is provided with a peculiar gearing operated by the mechanism of a clock, the face of which is exhibited upon the face of the globe. This gearing is connected with a disk, upon the rim of which are secured adjustable pointers, projecting through a circumferential slot in the base of the globe, and adapted to be directed by the revolution of the disk to the successive divisions in the various series marked thereon. The gearing is also connected with an electric alarm and is so constructed as to operate at any desired periods or divisions of time. The object of the invention is to provide a simple and economical globe for the use of schools, by which a number of facts and results and their causes may be readily demonstrated and easily acquired, and at the same time provide for its automatic action, and thereby, in addition, furnish an alarm for calling attention to any desired time or times.

PISTON WATER METER.—Frank Walker, Tombstone, Arizona. No 272,607. Dated Feb. 20, 1883. This invention relates to a new and useful water meter of that class in which reciprocating pistons work in a cylinder of known capacity. The invention consists in a novel valve and valve chamber, and the arrangement of parts therein whereby the pistons are operated and the valve reciprocated longitudinally, and it further consists, in connection with the valve and valve chamber, in a slotted connecting rod between pistons, and an intervening lever-valve whereby the strokes of the piston are transmitted to the register. In the formation of these buckets or flanges, two main points have heretofore been considered. The first is the impact of the stream, and the second its discharge. A good surface may be presented to the water, but the bucket may be so constructed as to hinder its discharge, which, by not being readily freed, retards the progress of the wheel. In like manner the buckets may free themselves easily but may not receive the stream to the best advantage. To these two points a third may be added—namely, the splash. No matter how readily the buckets may free themselves, there must be more or less splash on account of the force with which the water is directed upon them, and this splash not only takes away from the resulting or continued force of the water, but as an actual hindrance to revolution. In the construction of this bucket, this inventor claims that he gains all the advantages described in receiving and discharging the water and avoiding all splash.

TWO-WHEELED VEHICLE.—Geo. P. Kimball, S. F. No. 272,557. Dated Feb. 20, 1883. This improvement in two-wheeled vehicles consists in a novel construction of the shafts and in their relation to the axle and body. It consists also in a novel arrangement of the springs and the footboard in relation to the shafts, axle and body. The object is to provide an easy riding vehicle, which, on account of the construction and arrangement of its parts, will be both economical and effective.

DRESSING SAW-TEETH.—Stephen H. Chase, San Jose, Cal. No. 272,530. Dated Feb. 20, 1883. This is a novel device for jointing circular saws and more especially relates to a tool which is adapted to joint or dress the sides of the teeth. The invention consists in certain details of construction. The object is to provide a device for dressing or jointing the sides of the teeth of a circular saw, after they have been swaged, to bring them into line with one another and cause them to cut clean.

WATER-WHEEL BUCKET.—Charles D. Smith, Amador City. No. 272,592. Dated Feb. 20, 1883. This invention relates to a new and useful bucket for water wheels of that class which have their rims formed with, or have bolted or secured thereto, flanges or buckets, which receive the impact or force of a stream of water under pressure. The invention consists of a hollow or chambered bucket, provided with a central opening to receive the water, and separate and distinct discharge openings at the ends through which to discharge it outside of the plane of revolution of the wheel. The object of the invention is to utilize the entire body or stream of water by so receiving and directing it as to avoid all splash, and cause it to exert its force to the best advantage. The object may be better seen by a brief reference to the points to be observed in the construction of wheels of this class.

GAS PURIFYING SCREEN.—Emanuel M. Provancher, Vallejo, Solano Co. No. 272,582. Dated Feb. 20, 1883. The object of this invention is to expose as much of the body of lime to the gas as possible to provide an easy means for forming the screen and removing old or inserting new slats, and to have a ready means either to support or raise it.

NICKEL WIRE IN SILVER AND GOLD LACE.—Silver plated copper wire, as is well known soon loses its silver coating and assumes a disagreeable copper color and smell. Aluminum has been alloyed with silver to avoid this difficulty, but not with much success. A better method is that recently adopted by a German firm at Weissenberg, which makes use of nickel alone, that metal having first been deprived to a large extent of its brittleness. Later Messrs. Fleitman and Witte, of Iserlohn, made the discovery that the addition of a small quantity of other metals would render the nickel so ductile that that metal itself unalloyed could be drawn out into wire of the finest numbers and be scarcely inferior to copper. Wire has been drawn so fine that 18,000 meters only weighed 100 grammes (or 12 miles weighed about 3½ ounces avoirdupois). Ductile nickel differs from copper, so that the increase of price for increased sizes differs from that of the plated copper wire hitherto in use. For articles subjected to much wear and the action of the weather, this ductile nickel will be very useful. For the lace used on military uniforms the plated copper wire will go out of use entirely, as nickel wire would always keep white and no verdigris ever be formed. Great anticipations are made for it in other directions, too.

LADIES and all sufferers from neuralgia, hysteria, and kindred complaints, will find without a rival Brown's Iron Bitters.

POTELINE is a new substance, named after its inventor, and which he claims to be insusceptible of many useful applications. It is substantially a mixture of gelatine, glycerine and tannin. It is claimed to be absolutely impervious to the air. It becomes liquid, or nearly so, on being warmed, and assumes the contour of objects. The inventor has made corks of it which form an economical substitute for metallic capsules, and make a hermetic seal. He also recommends it as a preservative of meat, which, when treated with poteline at a temperature of 112°, is said to retain its freshness for several months. It appears to act by its ability to perfectly exclude the air when the meat is enveloped by it.

News in Brief.

PARNELL is coming to America.

GOVERNOR ALEXANDER H. STEPHENS, of Georgia, is dead.

The Mexican Central road has satisfactorily placed a loan of \$6,000,000.

LAST CHANCE is the name of a new town on the Northern Pacific road, 586 miles from Portland. The town is composed of one barber shop, three China wash houses, six restaurants, eight stores and only 32 saloons.

FOUR hundred workmen were dismissed from the manufacture of firearms at Steyer, Austria, on account of lack of orders from abroad. The total number employed will be reduced from 6,000 to 5,000. Many intend to emigrate to America.

THE Dominion Government, supported by the English Admiralty, is to put a cruiser on Hudson Bay this summer, to ascertain how much of the year Hudson Strait is open to navigation.

THE contemplated trip to California of Chas. A. Dana, and Simon Cameron and families is delayed by the illness of Cameron's son. They will start within a fortnight, traveling by the Southern Pacific.

THE reduction of the tobacco tax, provided in the internal revenue clause of the tariff bill, goes into effect on May 1st. The abolition of taxes on the capital and deposits of banks, bankers and national banking associations takes effect immediately; on bank checks, drafts, matches, perfumery, proprietary medicines, and the revised duties on imports, on and after July 1st next.

CHAMP ORR PUT VERIZPR.—There is for sale in this city, as will be seen by our advertising columns, a second-hand Rutherford Pulverizer, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it.

New Life

is given by using BROWN'S IRON BITTERS. In the Winter it strengthens and warms the system; in the Spring it enriches the blood and conquers disease; in the Summer it gives tone to the nerves and digestive organs; in the Fall it enables the system to stand the shock of sudden changes.

In no way can disease be so surely prevented as by keeping the system in perfect condition. BROWN'S IRON BITTERS ensures perfect health through the changing seasons, it disarms the danger from impure water and miasmatic air, and it prevents Consumption, Kidney and Liver Disease, &c.

H. S. Berlin, Esq., of the well-known firm of H. S. Berlin & Co., Attorneys, Le Droit Building, Washington, D. C., writes, Dec. 5th, 1881:

Gentlemen: I take pleasure in stating that I have used Brown's Iron Bitters for malaria and nervous troubles, caused by overwork, with excellent results.

Beware of imitations. Ask for BROWN'S IRON BITTERS, and insist on having it. Don't be imposed on with something recommended as "just as good." The genuine is made only by the Brown Chemical Co. Baltimore, Md.

PELTON'S PATENT Reaction Hurdy Gurdy Water-Wheel.

This Wheel will be guaranteed to purchasers to give 83% of the theoretical power of water. Send for circular to L. A. PELTON, Nevada City, Nevada Co., Cal.

Goods, and by the "GARLAND" IMPROVED SEWER GAS TRAP MFG CO., 1901 Broadway, Oakland, Cal. Cast Rights for sale.

NOTICE TO MINE OWNERS.

THE PACIFIC MINING AND REDUCING COMPANY, whose works are located at 410 Rich Street, and whose General Office is at 413 California Street, would respectfully announce to owners of mines of rebellious ores that they will either purchase for cash or receive ores for treatment at their works.

JAMES W. BURLING, Secretary.

WELLS' PATENT UNBREAKABLE LAMPS AND OIL FEEDERS.

A. C. WELLS & CO., Patentees,
Market St. Manchester, Eng.

OVER
150,000

Cast in first two years, superseding all others. Ask your Furnisher to get you them.

WRITE FOR LISTS.

Agents wanted in all parts. Liberal Terms.

Entirely superseding tin goods, as they Don't Leak or Break!

Adopted in the English Government and finest Railway Works and Steamship Companies in the world.

Sole Wholesale Agents for the United States,
FAIRBANKS CO., 140 Chestnut Street, Philadelphia, Pa.

CHAR. E. LLOYD.
J. S. BEARDSLEY.
BEARDSLEY & LLOYD,
REAL ESTATE AGENTS.
No. 912 Broadway Street,
Between 8th & 9th Sts., Oakland.

Particular Attention given to Negotiating Loans upon Favorable Terms. Acting as Agents for Buyers and Sellers of Real Estate, and the Management of Business for Absent Owners.

REMITTANCES to this office should be made by postal order or registered letter, when practicable; cost of postal order, for \$15 or less, 10 cts.; for registered letter, in addition to regular postage (at 3 cts. per half-ounce), 10 cts.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 509 South 10th St., Philadelphia. Branch Office—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

Ball Patent Valve,

LINK OR GOVERNOR

Engine and Locomotive Boiler.

1500 IN USE.

BEST AND CHEAPEST.

TATUM & BOWEN,

25, 27, 29 and 31 Main St., San Francisco
187 FRONT ST., PORTLAND.

THE ROLLER ORE FEEDER.

Patented May 28, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or sand clay alike uniformly, under one or all the stamps in a battery, as required.

In the Banker B. Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,
Sole Manufacturers,
327 First Street, SAN FRANCISCO, CAL.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, better than anything else. (Cost six cents per pound.) Address,

ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco.

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 23, 1883.

Mr. A. B. Paul:—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quicksilver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which glides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them.

E. G. McLEAN,
Superintendent Indian Spring Drift Mine.

H. H. BROMLEY,

Dealer in Leonard & Ellis' Celebrated

TRADE MARK

STEAM CYLINDER AND MACHINE OILS,
The Best and Cheapest.

These Superior Oils cannot be purchased through dealer and are sold direct to consumer only by H. H. BROMLEY sole dealer in these goods.

MINERS' HORSE-WHIM

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timber, thus avoiding all fram work. When required these whims are made in sections to pack on mules.

NATIONAL DUPLEX COMPRESSOR.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

Engraving.

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the Mining and Scientific Press, San Francisco at reasonable rates.

REMITTANCES to this office should be made by postal order or registered letter, when practicable; cost of postal order, for \$15 or less, 10 cts.; for registered letter, in addition to regular postage (at 3 cts. per half-ounce), 10 cts.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY, 21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

PACIFIC MACHINERY DEPOT.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR, —OR— VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street,
Nov. 6, 1882.

SAN FRANCISCO, CAL.

To Prospecting Quartz Miners.

Miners having reliable properties in California, and who are willing to give one-half of their interest in the same for suitable machinery, may benefit themselves by corresponding with me. Now wanted on this day: A decomposed quartz lode, where water can be had for power; also a mine sufficiently large and developed for a 40 Stamp Mill. Address,

ALMARIN B. PAUL,
Room 20, Safe Deposit Building, San Francisco.

VOLUME XLVI
Number 11.

Gold Discoveries in British Columbia.

As early as June 1856, Mr. Douglas, the Governor of Vancouver's Island, reported to the Secretary of State the discovery of gold in British Territory, north of the 49th deg. of latitude, and stated that the earnings of the diggers range from £2 to £8 per day. In consequence, however, of the hostile attitude assumed by the natives, the number of diggers was very limited. Altogether, this discovery attracted at first less attention than might have been anticipated; but, in December 1857, Governor Douglas reported that the Indians themselves were extensively engaged in the search for gold, and that the accounts which had reached Oregon and California had caused considerable excitement. It was not, however, until May, 1858, that a stream of immigration, sufficient to overpower the opposition of the aborigines, had fairly set in, and the British public learned for the first time, that the mainland of New Caledonia, as the district extending from the Red river to the Pacific was somewhat vaguely designated, was a rich auriferous country, which gave every promise of becoming a flourishing and important colony.

Beginning with the Fraser river, the main artery of the auriferous region, gold is known to exist, and has been worked at a great many places on its course, from a point about 45 miles from its mouth up to near its source in the Rocky mountains—in other words, from the 49th up to the 53d parallel of north latitude, a distance, taking in the windings, of some 800 miles. The union of the two branches forms the Fraser river proper. Adding the north branch, which is also a gold-bearing stream, the two will give a continuous stretch of auriferous territory, upwards of 1,000 miles in length, extending for many miles back into the country, but not including the tributary rivers which fall into the Fraser. In short, the river itself is known to be auriferous, and to pass through a gold-bearing country throughout its whole course. Gold is also found in many tributaries of the Fraser, of which no less than 59 are known.

These facts do not, however, by any means convey an accurate view of the extent of the area of the gold fields, because these observations are limited to the central portions only of the country, while the whole of the upper portion of British Columbia is said to be auriferous.

Besides the gold found in the beds and on the shores of streams, the Fraser itself and many of its tributaries are skirted by terraces which yield gold. These terraces, or "benches," as the miners call them, run at intervals along both sides of the river for miles in length, and recede where the mountains fall back into the valleys, varying in breadth from a few yards to several miles. These are objects of curiosity, and add much to the beauty of the scenery in which they occur. They are generally found on both sides of the river, at the same place, sometimes at the same elevation on both sides, sometimes at different elevations—high on this and low on the other side of the river; and in some places they are multiplied into several successive level platforms, rising one above the other as they recede from the bank. These terraces are composed of the ordinary alluvial deposits, loam, gravel, stones, sand, and boulders, and are thick masses, generally rising about 150 or 200 feet.

Gold

Gold is nearly always found in the metallic state, but never pure. A good crystal is considered a rarity. The octahedron and dodecahedron are the most common forms. Crystals sometimes acicular, through elongation of octahedral or other forms; also passing into filiform, reticulated, and aborescent shapes, and occasionally spongy from an aggregation of filaments; edges of crystals often salient. Cleavage, none; twins: twinning plane octahedral;

In metallurgical works the proportions of mercury to gold in amalgam vary greatly, owing to the size as well as the purity of the particles of gold which have been brought into contact with the mercury. It has been found in reduction works in California that the due percentage of mercury in the gold amalgam obtained varied from 36 to 85%. Nearly all the metallurgical products from lead, silver and copper smelting works contain gold, and especially those obtained from the smelting of argentiferous lead ores; but, as a general rule,

The hood is of cast iron and all the fittings to the boiler are of the best manufactured. The boiler and engine are secured firmly to a cast iron bedplate and weighing but eleven hundred pounds. It is shipped in one piece and is ready to run upon arriving at destination. There are but two sizes of this style of engine and boiler manufactured at present, the three horse and five horsepower. They are especially designed for nice work and are recommended to those desiring to run tank pumps, woodsaws, spice mills, desiccating machinery, arrastras, or small hoisting works. These engines are made in this city by Edward A. Rix, Nos. 47 and 49 Fremont street. At the same shop is manufactured a friction hoisting reel, complete with all attachments to connect with this engine and boiler for prospecting purposes. Those looking for small hoists for prospecting and who desire more power than given by a whim should examine these "Baby Hoists."

RIX'S IMPROVED VERTICAL ENGINE.

Also, massive and in thin laminae. The above forms usually occur in veins or lodes.

In alluvial soils, streams, rivers, and gravel beds, gold is generally found in flattened grains or scales and in rolled masses.

Hardness—25-3. Spec. gravity—15.6-19.5; 19.30-19.34 when quite pure (G. Rose.)

Gold is generally alloyed with silver in various proportions, and pieces from California, Idaho, and Nevada, have been assayed by Mr. George Attwood and found to contain as much as 50 per cent. silver; whilst the purest native gold from the same sources that were examined have assayed 97 per cent. pure gold and nearly 3 per cent. silver.

Gold is also found combined with copper, iron, bismuth, palladium, rhodium, and tellurium. Gold combined with mercury in what is generally termed gold amalgam. Gold is also found associated (or as an incidental ingredient) with certain ores containing iron and copper pyrites, mispickel, blend, and galena,

the quantity is too small to pay for extraction, as in many instances a "slight trace" can only be found by the most careful analysis.

Improved Vertical Engine and Boiler.

The vertical engine and boiler illustrated on this page is one rapidly coming into use on this coast. It does not differ in general plan of construction from many vertical engines and boilers now manufactured, but in finish and nicety of adjustment, and elegance of design it is far superior. The working parts to the engines are made from steel highly burnished; the connecting rod of phosphor bronze, which allows the greatest tensile strength while giving the smallest comparative diameter; all parts to different engines are interchangeable and made to standard gauges. The boilers are made from the best of iron, and the shell is fine sixteenths thick and all carefully rivetted and each tested to 200-pounds pressure.

Early History of the Comstock Mines.

EDITORS PRESS:—In your issue of Feb. 24th, your correspondent, Mr. Chas. Schuchard, in his interesting communication (page 126), refers to some notes on the discovery of the silver ore of the Comstock lode, which he thinks were published in the *Mining Magazine*. He is correct in this reference. One of the first notices of the discovery (if not the first), outside of the notices in the daily newspapers of that time, appeared in the *Mining Magazine* for January, 1860, (second series, vol. 1, page 221.) A short notice appeared also in the number for December, 1859. Both of these notices, and several others which followed, were written by myself as the editor of the *Magazine*. The first notice was based in part upon a letter from the correspondent of the *New York Daily Times*, over the signature, "Podgers," but known to me as Capt. Richard L. Ogden, who was early interested in the discovery, and was, I believe, at that time associated officially with Gen. Allen, the Army Quartermaster in California. In his letter of November 5th he stated that the vein had been traced over a thousand feet. The Walsh company had 1,400 feet, and next to this claim Bryant and Raymond had purchased 50 feet, for which they had paid \$400 per foot. By a later notice (page 242) it appears that on the 29th of November, 1859, over three tons of silver ore had arrived in San Francisco, and a share of 1-40th in the original location on the vein sold for \$10,000.

Shipments of ore to New York commenced early. Mention is made of several tons which arrived in January, 1860. It consisted of granular galena with copper pyrites in quartz, but contained grains and filaments of native silver (p. 323.) Some of these lots of ore sent to New York were smelted at the works of the New York Smelting Company, on Staten Island. On page 405 of the *Magazine* will be found a reprint of a communication relative to Virginia town and Washoe valley by Mr. F. Hughes, and on page 409, in a letter from "Podgers," giving an account in detail of the discovery and of the excitement, of Major Killey and his death shortly after making the assay. Residents of Grass Valley, Cal. as early as 1854, will remember this enthusiastic Mexican miner and assayer, who lived in Boston ravine, and had there one of the first Freiberg blowpipe assaying outfits seen in California. The same letter gives an account of the formation of the Ophir Company of which Mr. Ogden was Treasurer. The shaft was then 50 feet deep (p. 410.) About that time, I received samples taken from the Ophir mine of the black, brittle ore from Mr. Ogden; some fragments were crystalline, and, on examination, I found that they were crystals of *Strophantite*, or *Brittle Silver*, and announced it in the *Magazine* (p. 479.) This was the first scientific identification of this mineral species in that ore, and it had not been before that time known to occur in the United States.

WM. P. BLAKE,
Mill Rock, March 4, 1883.

CORRESPONDENCE.

A Gold-Producing Region.

EDITORS PRESS:—About seven miles south-east of Angel's camp, on the Stanislaus river, are the Garibaldi gold quartz mines, consisting of the Garibaldi South, the Andromeda, the Pharis and the Polaris, all true fissure veins of a strong and permanent character. They are situated on the great "Mother lode," which extends from Alpine Co., on the north, to Mariposa Co., on the south, and are enclosed in a bend of the Stanislaus river, forming a peninsula containing about 400 acres. The walls of these veins are slate and dioritic, or crystalline rock. The slates are highly metamorphosed, and contain gold. From 10 to 15 per cent. of the inclosed walls is pyrites of iron. The veins are the results of thermo-chemical springs, the pyritic matter in the walls causing a precipitation of the precious metals. The claims mentioned are each 1,500 feet in length, by 600 feet in width, the limit established by Congress in 1872.

The preliminary development of these unquestionably very rich properties has fairly progressed. A lateral tunnel has been run, crossing the Garibaldi South 152 ft. from its mouth, and forming the line of division between this mine and the Andromeda. The Andromeda has been drifted on from this tunnel, a distance of 150 feet. From the surface of this latter mine a shaft has been sunk 75 feet. On the Pharis an adit level has been run over 300 feet. The width of the Andromeda and Garibaldi South veins is from 20 to 25 feet, that of the Pharis and Polaris five to seven feet. The ore of the Garibaldi South and Andromeda is composed of quartz gangue, thoroughly disseminated with galena sulphurets. The ore of the Pharis and Polaris is also heavily impregnated with sulphurets. These sulphurets are worth at the dumps \$200 per ton. Though many assays of the average ores give higher results, yet by regular milling process they will yield from \$15 to \$30 per ton free gold.

The Stanislaus River Gravel Company, to which these mines are adjacent, consists of 220 acres of rich mineral land situated on both sides of the Stanislaus river, and includes two and a half miles of the river bed. This portion of the Stanislaus river has never been flumed, although, according to estimates of Wells, Fargo & Co's express agents, its banks at this point have yielded over \$8,000,000. The banks of the river having proved so rich, careful tests were made to ascertain the value of the bed. It was found that the vast wealth it contained could only be reached by draining the water from the river. A magnificent canal, the result of Chicago capital and enterprise, has been constructed, capable of carrying from 8,000 to 10,000 inches of water per minute. This canal will furnish fully 500 horse-power at the north-west end of Andromeda and Pharis mines, and more than requisite power for the Garibaldi South mine. It will be able to carry all the water of the river seven or eight months of the year. It has been cut through solid metaphoric rock to the depth of 12 or 13 feet, thus keeping it from the action of high floods and making it as permanent a structure as solid rock can make it. The course of the canal is from Soldier's Gulch south, traversing the entire length of Dusty and Gravelly bars. Along this portion of the river the practical work of taking gold from the exposed bed and deeper bars will be commenced as soon as the river has resumed its normal dimensions after the spring floods.

From the great difficulty and expense of turning this river, and the danger from floods before sufficient time could be obtained to wash the dirt and remove the boulders, the bedrock of the channel has been rarely reached. But there is not an authentic instance where it has been reached that the results failed to prove highly remunerative.

At a place about three miles above "Dusty bar" this river was flumed for a distance of three fourths of a mile, and gold to the amount of between \$2,000,000 and \$3,000,000, taken out of the bed of the channel, as shown by authentic records. A short distance below "Dusty bar" an Italian, in the autumn of 1881, succeeded in draining the river for a distance of 40 rods. He claims, by his own labor only, to have taken from \$500 to \$600 per diem, and even then he had not reached the bed rock of the channel.

The Stanislaus Gravel Co. is a close corporation, and the owners have never asked one extra dollar from the investing public to aid in the enormous expense of placing this valuable property in a paying condition. In any part of the country it would have probably been impossible to keep an enterprise of such magnitude and employing so many people, from public curiosity. But the owners, aware of the present well-founded feeling of cautions in regard to all new mining enterprises, determined to do the most essential work necessary to the success of the undertaking by their own private means.

F. W. STRATTON.

Garibaldi Mine, Calaveras Co. Cal., March 6.

The Postal Telegraph.

The Rev. Sidney Smith once said, there was a kind of men into whom you could not introduce a new idea without a surgical operation; and he might have added, that when an idea was once forced into the heads of some men, they could not be delivered of it without trepanning. This class of men seem to think that nature made a mistake in placing the eyes in the fore part of the head. Rooted in the past, they look backward. It is so easy to run in ruts, so uncomfortable to be jolted out of ancient habits. This sort of conservatism, or slow-motioned sluggish thought, lies athwart every scheme of progress and improvement, like a colossal mountain range, covered with eternal frost and snow, and chilling the country thousands of miles on both sides. The enterprising Hannibals, who would scale the Alps of prejudice and unthinkingness, have always had to fight their way over ice, and hew a path through rocks.

When Sir Rowland Hill first proposed the reform of the postal system of England by the establishment of a uniform postage rate of one penny, a noble lord who was then Postmaster General of Great Britain, exclaimed: "Of all the wild and visionary schemes that I ever heard of, it is the most extravagant." All the paleozoic men came to his aid and said: "Let well enough alone. Let us have no erratic tinkering with the postal system. Where will the Government revenues come from if we adopt this reform? The projector, undismayed by the jeers and ridicule heaped upon him, continued to press upon the public attention facts, statistics and arguments, until Parliament was forced to give the matter a patient and impartial investigation. The reform was adopted after a hard struggle, and proved an immediate and triumphant success.

The happy results in Great Britain soon awakened public attention in America, but the paleozoic men were on hand and raised a formidable opposition. The conditions of this country and Great Britain are so unlike, they said, that no inference from her experience can be made favorable to the scheme. Great Britain is a small, densely populated country, while we have an immense territory that is very sparsely settled. The postal service cannot be kept up at reduced rates over these wide areas. But the scheme finally prevailed, and postage went down from twenty-five cents to three cents, and instead of injuring the revenues, as predicted, the transmission of letters was increased more than twenty-fold the first year, and the plan succeeded beyond the expectation of the most sanguine.

The wonderful discoveries of science wrought out new means of transmitting intelligence, and placed another responsibility upon law-makers to secure their advantage for the people. Here, again, Great Britain took the lead, and by an Act of Parliament purchased the telegraphic lines throughout the whole kingdom and made them an adjunct of the postal system, bringing the benefits of telegraphic communication within the means of the poorest.

But this blessing was not attained without another struggle. The corporation lawyers, the men of black-letter traditions and ancient precedents, and the keepers of the legal sepulchers talked long and loud about the stability of contracts, vested rights, and the danger of paternalism in government, and all that sort of thing. The example of England has been followed by France, Prussia, Switzerland, Sweden and Belgium, and everywhere the governmental control of the telegraph has proved a cheap, efficient and advantageous means of communication for everybody. The people enjoy the greatest facilities at rates that seem absurdly cheap to a people accustomed as we are to high telegraphic tolls.

Though the inventor of the electric telegraph was an American, though the people of the United States were the first to adopt this method of conveying intelligence, it seems that we are destined to be the last enlightened country to enjoy its full fruition. This question has been in Congress at intervals for the past 15 years, and yet nothing has been done. A bill was introduced in the House during the late session, but, like its predecessors, it was smothered in the committee room. There is no excuse on the part of Congress for delaying this reform. It is no experiment. The policy has been tried by other countries, and proved a great success. If a postal telegraph is a good thing in Europe—is found to save time and expense where railroads can carry the mail in a few hours from one border to another—how much more beneficent it would prove in a country so vast as ours, where the best locomotives in the world could not pass from one extreme to the other in less than a week.

IMPROVEMENTS IN BLAST FURNACES.—Only ten years ago a blast furnace which would make 400 tons of metal per week on 600 tons of fuel was considered a big thing. We have blast furnaces in Pittsburg which produce 1,500 tons of metal per week on less than 1,500 tons of fuel. The old method of heating permitted the flame to pass out of the furnace stack at a temperature of 3000° F. We are now using the regenerating stoves in Pittsburg, and do not let the gases out until we have utilized all the heat except 200°.

A State Bureau of Labor Statistics.

Following is the full text of the bill creating a Bureau of Labor Statistics, which has received the Governor's signature, and has become a law. The institution may be of very great importance to the class it is intended to benefit:

The People of the State of California, represented in Assembly and Senate, do enact as follows:

Section 1. As soon as possible after the passage of this Act, and every four years thereafter, the Governor of the State shall appoint a suitable person to act as Commissioner of a Bureau of Labor Statistics. The headquarters of said Bureau shall be located in the city and county of San Francisco, said Commissioner to serve for four years, and until his successor is appointed and qualified.

Sec. 2. The Commissioner of the Bureau, before entering upon the duties of his office, must execute an official bond in the sum of \$5,000, and take the oath of office, all as prescribed by the political code for State officers in general.

Sec. 3. The duties of the Commissioner shall be to collect, assort, systematize and present, in biennial reports to the Legislature, statistical details relating to all departments of labor in the State, such as the hours and wages of labor, cost of living, amount of labor required, estimated number of persons depending on daily labor for their support, the probable chances of all being employed, the operation of labor-saving machinery in its relation to hand labor, etc. Said statistics may be classified as follows:

First—In agriculture.

Second—In mechanical and manufacturing industries.

Third—In mining.

Fourth—In transportation on land and water.

Fifth—In clerical and all other skilled and unskilled labor not above enumerated.

Sixth—The amount of cash capital invested in lands, buildings, machinery, material and means of production and distribution generally.

Seventh—The number, age, sex and condition of persons employed; the nature of their employment; the extent to which the apprenticeship system prevails in the various skilled industries; number of hours of labor per day, the average length of time employed per annum, and the net wages received in each of the industries and employments enumerated.

Eighth—The number and condition of the unemployed, their age, sex and nationality, together with the causes of their idleness.

Ninth—The sanitary condition of lands, workshops, dwellings; the number and size of rooms occupied by the poor, etc.; the cost of rent, fuel, food, clothing and water in each locality of the State, also the extent to which labor-saving processes are employed to the displacement of hand labor.

Tenth—The number and condition of the Chinese in the State, their social and sanitary habits; number of married and of single; the number employed and the nature of their employment; the average wages per day at each employment, and the gross amount yearly; the amounts expended by them in rent, food and clothing, and in what proportion such amounts are expended for foreign and home productions respectively; to what extent their employment comes in competition with the white industrial classes of the State.

Eleventh—The number, condition and nature of the employment of the inmates of the State Prison, county jails and reformatory institutions, and to what extent their employment comes in competition with the labor of mechanics, artisans and laborers outside of these institutions.

Twelfth—All such other information in relation to labor as the Commissioner may deem essential to further the object sought to be obtained by this statute; together with such strictures on the condition of labor, past, present and the probable future of the same, as he may deem good and salutary to insert in his biennial report.

Sec. 4. It shall be the duty of all officers of State departments, and the Assessors of the various counties of the State, to furnish, upon the written request of the Commissioner, all the information in their power necessary to assist in carrying out the objects of this Act; and all printing required by the bureau, in the discharge of its duty, shall be performed by the State Printing Department, and at least three thousand (3,000) copies of the printed report shall be furnished the Commissioner for free distribution to the public.

Sec. 5. Any person who wilfully impedes or prevents the Commissioner or his deputy, in the full and free performance of his or their duty, shall be guilty of a misdemeanor, and upon conviction of the same shall be fined not less than ten (10) nor more than fifty (50) dollars, or imprisoned not less than seven (7) nor more than thirty (30) days in the county jail, or both.

Sec. 6. The office of the bureau shall be open for business from nine (9) o'clock A. M. until five (5) o'clock P. M. every day, except non-judicial days, and the officers thereof shall give, to all persons requesting it, all needed information which they may possess.

Sec. 7. The Commissioner shall have power to send for persons and papers whenever in his opinion it is necessary, and he may examine witnesses under oath, being hereby qualified to administer the same in the performance of his duty, and the testimony so taken must be filed

and preserved in the office of said Commissioner; he shall have free access to all places and works of labor.

Sec. 8. The Commissioner shall appoint a deputy, who shall serve the same time and have the same powers as the said Commissioner as set forth in the preceding sections; he shall procure rooms necessary for offices, at a rent not to exceed fifty (50) dollars per month, and may provide the necessary furniture, at an expense not to exceed five hundred (500) dollars.

Sec. 9. The salary of the Commissioner shall be twenty-four hundred (2,400) dollars per annum, and the salary of the Deputy Commissioner shall be fifteen hundred (1,500) dollars per annum, to be audited by the Controller and paid by the State Treasurer, in the same manner as other State officers are paid; there shall also be allowed a sum not exceeding five hundred (500) dollars per annum for stationery, and other contingent expenses of the bureau.

Sec. 10. The sum of ten thousand five hundred (10,500) dollars is hereby appropriated out of any money in the State Treasury, not otherwise appropriated, for the expenses of the bureau for the first two years after its organization.

Sec. 11. This act shall take effect and be in force from and after its passage.

Descending Shafts.

The Engineer-in-Chief of French mines, M. Haton de la Goupilliere, has lately called attention to an appliance, invented by M. J. Raffard, for facilitating the descent of miners into shafts up to 30 fathoms deep. A winch is placed at the mouth of the shaft, and provided with a rope, which makes two turns around the barrel; while a second rope, provided like the first, with a hook at each end, doubles the first by being hitched on to it. The miner who wishes to descend attaches a sack of sand, weighing about a cwt., to one of the ends of the winch rope and lets it down to the bottom of the shaft with the end of the second cord, which remains attached to it. He then passes the hook of his rope over a knot made about three feet from the end, and takes his seat by passing his leg through the loop thus formed, after having hitched on the loose end of the second rope. In this way an endless rope is formed, the difference between the weight of the man and that of the sack of sand remaining constant. The miner allows himself to descend slowly at first, keeping in his hands the two ropes; then, when the sack leaves the bottom, he lets himself go more quickly, but keeping the rising portion of the rope between his legs. As he nears the bottom he slackens the pace, seizes the rising rope with his hands and brakes himself till he stops; and then he attaches, by its end, the rope he is upon, so as to keep the sack suspended. When he wishes to reach the surface again he takes his seat as before, pulls on to the second rope, to which the sack is attached, and, by exerting an effort only slightly greater than the difference between his weight and that of the sack of sand, he rises easily at a speed of about two and a half feet per second. When 10, 20 or more men want to descend at once, two men go to the handles of the winch and let down the miners one by one, each taking care to keep the second or safety rope within reach for holding on to in case of accidents. When only three men, including those at the winch, remain to go down, the last but two attaches a weight of 66 lbs., consisting of coal or ore, to the end of the rope. The last man but one descends, aided by the last man at the winch; arrived at the bottom, the former hitches the second rope to the end of the winch rope and hangs the cwt. sack to the hooks, when the last man descends in the manner already described.

Seasoning Wood.

Wood requires time in which to season very much in proportion to the density of the fiber. But this rule is not without an exception, for pitch pine, which is not at all a densely fibered wood, requires a long time in which to season, even when the process is conducted under favorable conditions.

This occurs in consequence of the resinous character of pitch pine, the resin clogging the pores of the wood and thus stopping up the channels through which the moisture would otherwise exude. There are some woods—and mahogany, ebony, and some other of the tropical woods are of the number—that even in their living state contain very little moisture.

Plants that are of slow growth contain less moisture when in a living state than do those whose growths are rapid. A mahogany tree requires 500 years in which to mature, and, as a consequence, its texture is exceedingly dense. Being dense in texture, it requires a long time to properly season, and during that lengthened period it shrinks very little. Mahogany should not be kept longer than necessary in the log, because inasmuch as the outside portion of a log contains the greatest amount of moisture, and it being the exposed part, it will, as the wood dries, shrink more than the inner wood, and so, to allow for the outside shrinking, outside shakes will and must occur.

The same remark applies with equal force to all log timber, but we name the circumstance in connection with mahogany particularly, for the reason that it is a general practice for some to keep their mahogany logs for a long time in an unsawn state.

MECHANICAL PROGRESS.

Invention Helps Labor.

The evidence is cumulative of the fact that invention and the multiplication of machinery creates an increased demand for labor, instead of having the opposite effect, as is held by many. One invention, or one new machine, opens the way for another, and either very often calls into existence an entirely new trade. Our contemporary, the *Wood Worker*, speaks of the scroll saw, a very simple instrument, but one which nevertheless has made room for quite a large business for its own manufacture, besides creating many new wants, which calls for an outlay of labor, which would never have been needed had it not been for that little invention.

These saw blades are often of a mere ribbon-like thickness, with teeth invisible to the eye, and perceptible to the touch only. As a dozen blades are supposed to accompany each of the 200,000 machines already in existence, that would have called for the manufacture of over 4,800,000 blades; and as each sawyer requires them by the dozen, if not gross, owing to their liability to break, the number manufactured is simply amazing. The low price at which they are produced, is, however, still more astonishing, considering the work required of them. The demand for scroll-saw patterns also keeps busy a large number of men. Then the demand for fancy woods created by the popularity of the scroll saw is something stupendous, firms having to send their orders at least six months in advance to secure a stock. The saw mills receive the woods in the log from the different sections where they grow. For fancy scroll sawing, Central and South America supply the rosewood, tulipwood, cocobola, amaranth and satinwood, and Mexico the mahogany and Spanish cedar. White holly, walnut, oak, and ash are domestic woods. The woods are sawed on veneer saws, and, after drying, are planed to the required degree of thickness, sometimes to one twenty-fourth of an inch.

A COTTON-PICKING MACHINE.—There appears to be a strong probability that the long sought for machine that will do away with the expensive outlay of labor heretofore required for gathering the cotton crop, has at last been realized. Mr. Ransom, statistical agent for South Carolina, describes a cotton-picking machine, and believes, from its success in a recent field trial, that the inventor, Mr. E. B. Hazleton of Charleston, has solved the problem of picking cotton by machinery. The implement somewhat resembles a long wagon on two wheels, from whose nave motion is conveyed by a chain hand, horses or mules furnishing the motive power. The pickers are toothed steel disks revolving between two wooden disks; the latter prevent unopened bolls, foliage, etc., from entanglement, while the fibers of the blossom, dropping even but slightly between, are caught, drawn entirely in, and taken cleanly from the boll by the teeth of the swiftly turning metal. A revolving brush removes from the teeth the fibers, which fall upon an endless apron and are conveyed to the body of the machine. As the machine moves forward, a V-shaped device converges the plants to the pickers. The shaft on which the latter revolves is inclined in such a way that the blossoms at any distance from the ground are reached. Motion is also conveyed to brushes on the front of the implement, by which sand and dust are removed from the plant. If the above machine proves a practical success, it will be almost as important to the cotton industry as was the invention of the cotton gin.

IS PAPER TO BE THE RAIL OF THE FUTURE? This question is seriously asked by the *Boston Journal of Commerce*, and answered by that paper as follows: It is well known that one of the best materials for car wheels is paper. It is now stated that paper can be utilized for the manufacture of rails, in place of steel, which has almost displaced iron. It is said in favor of the new material that the cost per mile will be less by one third than that of steel, and it will last much longer, being almost indestructible. There is no expansion or contraction from heat and cold, consequently no loose or open joints; and, being so much lighter than steel or iron, the rails can be made longer and connections perfectly solid, making the road as smooth as one continuous rail. The adhesion of the drivers of the engine to this material will be greater than that of steel, consequently the same weight engine will haul a larger load. There will be a great saving of fuel, and the smoothness of the rail will lessen the wear and tear of rolling stock. The rails are made wholly and entirely of paper, and so solid that the sharpest spike cannot be driven into them. The action of the atmosphere has no effect on it, will neither rust nor rot, and, with paper wheels and rails of the same material, our palatial trains will glide over the prairies at the rate of 60 miles an hour with as little jolt and jar as on an ocean steamer.

SHAFTING is continually getting out of line or of level, from one cause or another; the walls of the building may settle, or the floor may be depressed in one spot by an unusual weight; a heavy strain by a belt may cause the cutting of a box and consequent derangement of a line. Frequent periodical inspections should be made to readjust bangers and brackets, if necessary, and to ascertain if there is undue strain on any particular portion. Neglect of these duties will surely cause waste and expense.

Torsion Tests of Cast Steel.

Some very careful tests have been recently made, to ascertain the relative resistance to torsion of tool cast steel in its unannealed form, as it comes from the manufacturer and is cut off the bar; also in its annealed condition; and as hardened for tool purposes to be used on iron, taps, reamers, drills, and similar tools that are worked by torsion.

It is not generally supposed that hardening and tempering cast steel increases its torsional resistance, on the contrary it is usually accepted that resistance to torsion depends mainly on toughness—the coherence of fibers when twisted—and that this toughness is much diminished by the process of hardening. But in the tests to which reference has been made, from a number of different manufacturers, the specimens that showed the least torsional strength, when hardened, were yet one and a half times stronger, or resistant to twisting, than unannealed specimens from the same brand. To be more exact, the figures for the unannealed were 5,114, the annealed 5,166, and the hardened 7,596, being an increase in torsional strength of the hardened and tempered specimens over the annealed and the unannealed of more than 33 per cent.

Other specimens—those of different brands—showed a still wider difference between unannealed and hardened conditions: as of 5,010, unannealed, and 8,418, hardened; 5,346, against 8,814; 5,124, against 7,920; and of 5,100 against 8,232. These figures may represent pounds, as they actually did in the tests, the pieces tested being of round steel minus five-eighths of an inch diameter, with a distance between shoulders of two and three eighths inches. The hardened specimens had been hardened and then drawn to a straw color, leaving them as hard as any tempered tool used for working metals, and inferior only to the file, which is not tempered, or drawn, at all.

One of the peculiarities of the tests was that so light a difference existed between the torsional strength of unannealed steel and that which had been carefully annealed 24 hours, the results showing slightly in favor of the specimens tested as sent directly from the bar. The following shows the comparison:

Unannealed.....	5,514	5,610	5,346	5,124	5,100
Annealed.....	5,166	4,572	4,864	4,128	4,552

From this it appears that no increase of toughness, or of resistance to torsion, comes from annealing cast steel. But annealing is valuable in rendering the steel more amenable to the action of the cutting tool.

A CONTINUOUS STEAM ENGINE RECORDER.—A machine has recently been patented in England, and has also been introduced into this country, by which an accurate record is kept of the time of starting and stopping of an engine, with the variations of speed for every minute. The device is very simple and requires but little attention. The clock work has to be wound up only once a week. The record can be taken off by any office boy, and the device can be placed at a safe distance from the boiler, so as not to fail in its report of everything connected with any accident, etc. As an evidence of what it will do we copy the following: A gentleman having one of these instruments in use says: "I had had my clock at work a few days when I was one morning surprised to find it making a singular figure. I went to the engineer and asked what was wrong with the engine? He did not know that anything was wrong. We counted the strokes and found the speed right, viz., 30½ strokes per minute. But, said I, some moments it is running at 31, and other moments at 30. Last night when you stopped at 5:30 it was running all right. What have you done to the engine since? He said he had packed the throttle valve. I found upon examination, that the packing was too tight, and that the governor-balls had not the power to move the valve spindle until they had attained a considerable increase or decrease of speed. We stopped the engine, eased the packing, and started again, and it is duly recorded, and may be seen now, the day, hour and minute we stopped, together with the improved performance of the engine after restarting."

MOLECULAR STRUCTURE OF METALS.—It is generally thought that the crystalline structure does not exist in metals which have been drawn or rolled. M. Kalischer has undertaken a series of experiments with cadmium, tin, copper, iron, steel, etc. He has arrived at the conclusion that the crystalline state corresponds to the natural molecular structure of metals. This state may be modified more or less easily by mechanical labor, but it is commonly re-established under the influence of heat. In some metals which have been drawn into wire the heat, while re-establishing the crystalline structure, increases at the same time the electric conductivity.—*Chron. Industr.*

THE NEW NAIL MAKING.—We have already, in these columns, made quite full reference to the proposition of the nail makers in Wheeling and Pittsburgh to hereafter employ mild Bessemer steel instead of puddled iron in the manufacture of nails. It is now said that Bessemer steel nails, to do the same work, will not weigh much more than half as much as those made of iron, and furthermore, that a Pittsburgh mechanic has invented a machine that will cut them more than twice as fast as the machines heretofore in use.

SCIENTIFIC PROGRESS.

Ancient Mode of Baking Walls.

Among the recent discoveries at Hissarlik, by Dr. Schliemann, are the remains of buildings which he supposes to have been temples. Nothing, he says, could better prove the antiquity of the buildings than the fact that they were built of unbaked bricks, and that the walls had been baked after they were laid up, by huge masses of wood piled up on both sides of each wall and kindled simultaneously. Each of the buildings has a vast vestibulum, and each of the front faces of the lateral walls is provided with six vertical quadrangular beams, which stood on well-polished bases, the lower part of which were preserved, though, of course, in a calcined state. Dr. Schliemann maintains that in these ancient Trojan temples we may see that the *auto* or *parastates*, which in latter Hellenic temples fulfilled only a technical purpose, served as an important element of construction, for they were intended to protect the wall ends and to render them capable of supporting the ponderous weight of the superincumbent crossbeams and the terrace. Similar primitive *auto* were found in two other edifices, and at the lateral walls of the northwestern gate. It was also discovered that the great wall of the ancient Acropolis had been built of unbaked bricks, and had been baked like these temple walls. According to Dr. Schliemann, a similar process of baking entire walls has never been before discovered, and the *auto* in the Hellenic temples are nothing else that reminiscences of the wooden *auto* of old, which were of important constructive use.

Analyzing Blast Furnace Gases.

Mr. J. E. Stead, F. R. S., recently read a paper before the North of England Institute of Engineers on a new apparatus designed by himself for analyzing blast furnace gases. The apparatus is in two portions—one portion being used for collecting samples of gas from the mains, and the other portion for dealing with it in the laboratory.

After describing his device, Mr. Stead gave some valuable information in regard to the operation of blast furnaces. Among other things, he stated that during the production of one ton of pig iron combustible gases weighing nearly seven tons pass off from a Cleveland blast furnace, and that the calorific power of these gases is equal to that furnished by the combustion of 11½ hundredweight of coal. In the production of one ton of pig iron, five and a half tons of air are forced into the furnace, and the combustible gases drawn off from the top of the furnace require four and three fourths tons more air to complete their combustion. The total final products of combustion weigh 11½ tons, and these pass into the atmosphere as waste gases. Mr. Stead advocated strongly the systematic examination of blast furnace gas, stating that he had occasionally detected that one third of the combustible gas produced was passing into the atmosphere unconsumed. This was equivalent to throwing away about 70 tons of coal per week for each furnace producing 400 tons per week of pig iron.

Mr. Stead, read another paper at the same meeting as above. "On a Rapid Method of Estimating Phosphorus in Iron." He described the old method of testing for phosphorus, which occupied two days for each estimation. He then explained a new plan he had devised, whereby the same results can be obtained in two hours. In testing for phosphorus in basic steel, there is a special advantage in dealing with such material because it contains no silicon, and under such circumstances the phosphorus can be determined in a single hour. The principal saving of time arises from the absence of any necessity for artificial drying.

THE LATEST ELECTRICAL DISCOVERY.—The Rev. Mr. Gilbert, during an address at Christ church the other night, remarks the *Otago Times*, while speaking of the telephone, asked his audience if they would be astonished if he were to tell them that it was now proved to be possible to convey by means of electricity *vibrations of light*—to not only speak with your distant friend, but actually to see him. The electroscope—the name of the instrument which enabled us to do this—was the very latest scientific discovery, and to Dr. Gndrah, of Victoria, belonged the proud distinction. The trial of this wonderful instrument took place at Melbourne on the 31st of October last in the presence of some 40 scientific and public men, and was a great success. Sitting in a dark room, they saw projected on a large disk of white burnished metal the race course at Flemington with its myriad hosts of active beings. Each minute detail stood out with perfect fidelity to the original, and as they looked at the wonderful picture through binocular glasses, it was difficult to imagine that they were not actually on the course itself and moving among those whose actions they could so completely scan.

PHOTOGRAPH OF THE LATE COMET'S TAIL AND STARS.—Dr. Gill, at the Cape of Good Hope, succeeded in photographing the comet's tail, and with it 50 stars that were seen through the tail. The plate was exposed 140 minutes, and was kept up to the motion of the earth by clock-work.

Electricity in Mills.

It is well known that the electricity generated by the machinery of some manufacturing establishments is a source of great annoyance, and sometimes of positive evil. Hence it may be interesting to learn that a means has probably been devised which will free the machinery in mills from electricity which is thrown off from the belts. At the suggestion of Edward Atkinson, of the Boston Manufacturers' Insurance Company, says the *Boston Journal of Commerce*, F. W. Whiting has made a study of the subject, and has in operation at the office of the company his device for collecting this electricity and discharging it to the earth. The principle employed is that of the Leyden jar. The machinery is connected by a No. 18 copper wire in a circuit, and this circuit is connected with the gas and water pipe, and thereby with the earth. The machinery is discharged by this wire. As the belts are generating the electricity and throwing it out constantly, a collector, as it is called, is arranged in front of the belt and picks up the fluid, which is also conducted to the earth. In other words, the earth, being the great sponge for the electricity, it seeks that home rather than to attack the machinery. In the exhibition of the principle on a portion of a spinning frame, the cotton fiber is highly electrified, but on attaching the collector it is entirely discharged. Where the collector is applied to a speeder there is none of the annoyance so common in that portion of the card room. In applying this principle to the woolen cards it will probably be to arrange a conductor that will take the electricity from the surface of the condenser and into the iron frame, and from there to the earth. Mr. Whiting intends suggesting a form of appliance for different kinds of machinery. The device is now in use, and will not be patented, and, furthermore, the inventor offers to give all necessary information as to the manner of the construction and use of the device.

AN OBSERVATORY FOR OAKLAND.—An observatory for astronomical observations will be erected in Oakland by W. H. Jordan, who expects that the structure will be completed and the instruments in place by September. The tower will be 40 feet high, surmounted by a revolving dome of galvanized iron 12 feet high, with clock attachment and micrometer for the purpose of regulating the movements. A brick pier 47 feet high will run through the center of the structure to insure a firm foundation for the telescope in the dome. The telescope has been ordered to be made by Alvin Clark & Son, of Cambridge, Massachusetts, at a cost of \$3,000. The instrument will have a barrel 10 feet in length, with an object glass eight inches in diameter. The diameter of the object glass in the Davidson observatory is six and one fourth inches. The plans for the observatory were shown to Prof. George Davidson, who says that this plan fulfills all the essentials required for mounting, using and protecting the proposed equatorial telescope, transit, etc. Until the Lick observatory is completed the proposed Oakland observatory will be the most complete affair of the kind on the coast. The money for the observatory and the contents is subscribed by a gentleman of Oakland, who prefers that his name remain unknown for the present. One condition of the gift is that the observatory be located on some public square.

ANCIENT MANUSCRIPTS.—Many ancient manuscripts of untold value are believed to be stored away in the monasteries of Greece. A loss that will never be understood to its full extent has just been sustained in the destruction of the monastery of Vatopedi, which took fire through the carelessness of one of the monks, and, in the absence of any appliance for extinguishing the flames, was speedily burned to the ground. Several thousand Byzantine manuscripts were consumed in this fire. To prevent such irreparable losses in the future, the Greek Government has sent two Athenian professors, Findiklis and Kalogeras, who are experts in deciphering old manuscripts, to examine the libraries and archives of the monasteries, and to send such manuscripts as they find of value to the national library in Athens. These gentlemen report that they have already discovered a great store of parchment treasures in the monastery of Dusiko, among them some of ancient Greek authorship. It is said that they have found an unquestionable tragedy by Eschylus and one by Sophocles.

REASONING ANIMALS.—We confess that the two points which have always struck our mind as distinguishing the nature of brutes from that of men have been their inability to worship God and to kindle a fire. It would be folly to deny that brutes could reason. A sheep dog who wants to head a band of sheep in a narrow lane will jump over a wall and run along the other side until he has reached the exact spot occupied by the sheep at the head of the flock, and then jump back in order to drive them home. A colley who was fond of going out with a carriage, would go and hide himself as soon as he heard the order for the carriage given, so that he might not be tied up. If we analyze these and many other instances of sagacity, we cannot help admitting that a brute's mind is capable of two or three steps of reasoning. On the other hand, no animal ever manufactured a tool or weapon, even of the simplest kind; and it is doubtful whether a gorilla himself, supposed to be our nearest neighbor, uses a walking cane.—*London Spectator*.

100 ft, showing a fine vein of ore in the bottom, 20 inches wide. It is the intention to sink 30 ft more and then commence drifting on the ledge.

FROM DEEP SPRING.—N. Gilbert and Billy Hedge were in town to-day, from Deep Springs district, laying in supplies. Mr. Hedge speaks in the highest terms of the general prospects out that way.

THE ELGIN MINE.—This mine was located in the Nevada district about one year ago. It is situated eight miles north of the Keynote mine, and about 16 miles from Independence. No work of any consequence has been done on the claim until a short time ago, when the locators, Messrs. Baker, Barnes and Keyes, commenced operations. The vein is very favorably situated for working both the mine and ore, being within one and a half miles of plenty of water and wood. The ledge shows itself on the surface for a distance of 1,000 ft, and, at the point where work has been commenced, the vein shows a width of three ft of rich gold quartz.

MARIPOSA.

PROSPECTS BRIGHTENING.—*Gazette*, March 10: The prospect of the Hite Gold Quartz Co., resuming work and going ahead again as formerly appears fully assured. According to a mortgage filed here in the Recorder's office on the 8th inst., the company has secured a loan of \$150,000, which is secured by bonds payable three years from date with interest at 6 per cent. The mortgage recites that this loan is made for the purpose of "securing the debts heretofore contracted or which may hereafter be contracted." This would seem that the dark cloud which has for some time past been hovering over Hite's Cove and the mines therein has been dissipated, and sunshine of prosperity once more beams upon that locality.

PLUMAS.

CRESSENT MINE.—*Greenville Bulletin*, March 10: The work of getting up the new hoisting machinery is progressing rapidly; the unusual character of the present season has led to a change in the original plan; at first it was intended to arrange for hoisting with water power alone, but now either steam or water can be used as circumstances may require. This change has been made with very little outlay over the original estimate; the course having been determined upon before the work had been so far toward completion as to render much alteration necessary; the shaft will be sunk to a total depth of 500 feet, with levels run from each successive depth of 100 feet.

CHEROKEE MINE.—Cherokee stock is still quoted in New York; why it should be quoted at all is one of those things that no fellow can find out. With everything movable sold and taken away, the mine in its present condition is not worth two cents per share; it is quoted at six.

SAN BERNARDINO.

SUE.—*Calico Print*, March 10: Work is progressing on this fine claim. They have run a drift in 15 ft, the ledge measuring four ft. Besides the large quantity of first class ore already taken out and shipped to San Francisco they have 300 sacks of second class ore ready for the mill. The rich ore body of nearly solid black metal which they have struck continues to hold out, and the indications are that there is an immense quantity of the same quality of ore in the ledge, enough to yield a fortune to all the parties interested.

LITTLE WATERM N. owned by Robt. Anderson, and situated below the Sue. Work was commenced on this claim several days ago, and the ore taken from it is exceedingly rich.

THUNDER.—Mr. Knox is now working on this mine, and is taking out very fine ore, which resembles that of the Little V.

ENCHERQUER.—This claim was recently opened by the Briesen Bros., and is looking very favorable. They are taking out some fine ore, similar to that of the Occidental.

BLUTCHER.—Owned by Swain & Bland, and is situated about one and a half miles from town. Ten men are at work on night and day shifts running a cut, which is 40 ft long, and sinking a shaft, down 37 ft. Ledge matter five feet wide. Thirty-five tons of good ore sacked. This claim is a fine prospect.

SILVER KING.—Connection has been made between the winze level and the summit winze, making a clear way at the west end. The Cunningham shaft is now down 150 ft. They will be shipping about 25 tons a day in about two weeks. Every thing is progressing finely in the mine, and the ore assays average well.

SALE.—The Pioneer Quartz Mill at Hawley's Station, owned by Sherman & Somer, has been bought by the Silver Odessa M. Co.

ORE AND BULLION SHIPMENT.—The amount of ore and bullion shipped from this point is constantly increasing. Last Tuesday 22 tons of first class ore were shipped from the Oriental mine, 20 tons from the Garfield, and 20 tons from the Humburg. The same day 337 pounds of bullion were shipped from the Pioneer mill, at Hawley's Station, valued at \$5,000, being the returns of the Silver Odessa ore. The ore from this mine mills \$95 to the ton. Nine sacks of bullion passed through this station from Providence, its destination being New York city. They weighed about 1,200 pounds, valued at about \$16,000.

ELLENBURG.—The mines in this locality are looking unusually well. Two men are prospecting for ore on the Snow Bird with good success. The Cuba boys are feeling elated over the millings of their last ore, which went beyond their expectations, and are now taking out ore on the Triangle. The Mary Bell is progressing under the supervision of Messrs. Childs & Roberts, and bids fair to be one of the bonanzas of the camp. The San Houston No. 3 is still being worked and is looking well. We saw some very rich ore brought from San Houston No. 1 by Messrs. Sweetzer, Richardson & Wilkinson, who report it the biggest strike ever made in this camp. We will now pass over the hill to where we find John McBride with four men working on that rich prospect, the Plutarch, which is turning out the blue silver in considerable quantities. The Taggart mine is working four men and still continues to show that beautiful red and blue silver and every indication of a first-class mine. As we go down the canyon on our way home we find Mr. Askew digging out ore on the Neveweat. On the whole we have no reason to complain of our outlook.

SIERRA.

A NEW DEPARTURE.—*Sierra Tribune*, March 8:

The determination of the Harlem M. Co. to erect chlorination works at their mine, is a move in the right direction. It is a well known fact that, what to-day are some of the best paying mines in Nevada county, were a constant drain on the pockets of stockholders until the method was adopted of saving sulphurets, and by building their own chlorination works reduced them at a small cost, thereby adding largely to the gold yield. Quartz miners in this county stick to the "old way" with a wonderful degree of pertinacity. It is only an exceptional case where ore is found that will give its full yield by the ordinary amalgamating process, and strange as it may seem, the new methods of working gold ores, which have been introduced with such grand success in adjacent counties, have never had a trial in Sierra county. A mine like the Harlem, that gives a yield of five per cent. in sulphurets, valued at \$500 per ton, is certainly badly managed when the sulphurets are allowed to run to waste, as has been the practice for several years past, or, in fact, since the mine was first opened. However, the present managers of that property are going to work in the right way, and we believe that the new departure will not only add largely to the value of the Harlem mine, but will give a greater value to the whole quartz interests of our county.

GOOD ROCK.—T. H. Smith was over from Alleghany last week. Mr. Smith had with him some samples of ore recently taken from his mine, the Osceola, located on Kanaka creek. The quartz exhibited was very rich in free gold, and of the same character as rock taken from some of the wonderful bonanzas developed in that section during the past few years. Mr. Smith is now engaged in running a tunnel to the ledge 25 ft below the croppings. This tunnel is expected to open up a fine body of ore.

TUOLUMNE.

NEW CLAIM.—*Tuolumne Independent*, March 10: A new claim is being opened and worked by Messrs. Hardy & Rushing, in the neighborhood of Saratoga Diggings on a spur of Table Mountain—the lead being one of two that ran in and swelled the grand channel near Mountain Brow. They have tapped the diggings by a tunnel—the channel being about 20 ft wide. The diggings are good for \$5 per day per man.

A new quartz mill is on its way from San Francisco to the "Oakland" mine, which is situated in the neighborhood of Nate Arnold's mine, above Columbia.

Nevada.

WASHOE DISTRICT.

UNION CON.—*Enterprise*, March 8: The joint Sierra Nevada east crosscut on the 2000 level is being extended at the rate of 25 ft per week. The face is now in softer material, and streaks of quartz giving low assays are again being cut. The joint Mexican east crosscut on the same level continues in favorable vein material, carrying occasional stringers of low grade quartz.

OHMIR.—The station at the 3000 level is being lengthened some feet, in order to give more working room, and a crosscut will be started east next Monday.

MEXICAN.—Good headway is making in the joint Union Con. east crosscut on the 2000 level. The face is in vein material showing occasional feeders of quartz.

SIERRA NEVADA.—A chamber for a pump is being cut out on the 2700 level, and the east crosscut on this level is being timbered up.

HALE & NORCROSS.—The joint Savage north drift on the 2600 level is again cutting seams and bunches of quartz giving low assays. It now has less than 100 ft to go to reach the south line of the Savage.

SAVAGE.—The north drift on the 2600 level, joint with Hale & Norcross, is making good headway, and is in a favorable formation. Feeders of quartz are again beginning to be cut which show some metal.

CALIFORNIA.—Joint Ophir east and west crosscuts have been commenced on the 2900 level.

POTOSI.—Day before yesterday the drill tapped a strong flow of hot water in the face of the main south drift on the 2600 level. The hole was plugged up, and the drift turned more to the east.

CON. VIRGINIA.—Good progress is being made in the southeast drift on the 2500 level, though it is wet and very hot at the face. There has been no increase of water since the resumption of drifting.

YELLOW JACKET.—The water is again rising slowly at the new shaft. At the Winter's shaft over 70 tons of ore per day are being raised. Some paying ore is being found in the prospecting drifts.

NORTH GOULD AND CURRY.—The usual progress is being made in the west crosscut on the 2500 level and the material encountered is growing more favorable in appearance.

UNION SHAFT.—The new pumps are working well and smoothly. The retimbering of the tank station at the 2300 level is about completed.

ANDER.—The west crosscut is in a mixture of quartz and porphyry. The raise from the east drift is yielding some low grade ore.

UTAH.—The west crosscut on the 1300 level is being extended at the rate of about 25 ft per week. The ground continues dry.

ALTA.—Good headway is making in the drain drift that is being run out to connect with the south branch of the Suro tunnel.

BERNICE DISTRICT.

LAVELY CAMP.—*Battle Mountain Messenger*, March 8: From parties just in from Bernice District we learn that the prospects are flattering for a lively camp at that place during the coming summer. The ledge has been stripped in the tunnel about 200 ft and shows up well. Two tunnels will be started right away to cut the ledge at a greater depth than the present workings, the lowest one tapping the ledge at a depth of over 300 ft from the present workings. The Starr-Grove mill being hauled from Lewis to the new camp will be running inside of two months. Wood and water is plenty in the vicinity and the ore free milling, averaging about \$60 per ton. The cost of mining and hauling to the mill is small, and we look for Bernice district to become a large bullion producer in a short time.

THE ROAD.—*Silver State*, March 10: In view of the fact that Bernice district is likely to be a lively camp and producing considerable bullion at an early

day, our citizens are contributing to a fund to be used for repairing the road. Bernice is situated a few miles east of the Humboldt salt marsh, almost due south from Winnemucca. There is a natural road down Grass and Pleasant valleys to the mines, no mountains intervening. Teamsters say there are a few places on the road, where mountains streams wash out gullies at this season of the year that ought to be repaired, and then the road will be as good as any of equal length in the State.

CHERRY CREEK DISTRICT.

THE SITUATION.—*White Pine News*, March 10: Since our last there has been little or no change, so far as people here know, in the Star affairs. At one time this week the engineers and pump men quit and the works were closed down, leaving the pumps where they were. After a time other counsels prevailed, the machinery was put in motion with the view of raising the pumps and leaving the mine in the best condition possible. This, we are informed, was accomplished yesterday, and the mine abandoned. So far no intimation has come from San Francisco as to what the company proposes to do, if we except a letter from Gen. Williams in which he stated that for the past five years he and his company had lost a great deal of money here, and now that our people might share a part of the loss. This is consoling, for the people who have been carrying that company had made millions out of the Star; we wonder if Mr. Williams would be so generous as to divide with our people? We think not.

LOOKS WELL.—Miners tell us that at no time within the past four years have the lower levels of the Star mine looked so well as at present, and they cannot conceive how any crowd of sane men could act so foolishly as to permit so promising a piece of property as the Star to fill up with water and go to destruction. But it is the mandate of the powers that be, and if they can stand it, surely other people ought to be satisfied, provided they pay up what they owe. But this is just what the managers of the Star are trying to evade. To us the matter looks like the man who is said to have cut off his nose to spite his face. "Whom the gods would destroy they first make mad," is of heathenish philosophy, but very applicable to the Star management.

COLUMBUS DISTRICT.

NORTHERN BELL.—There is an improvement in the face of the east drift from the bottom of the winze from the fifth shaft level. The drift has been extended 10 ft, and is showing 18 inches of high grade sulphurets in the face. A new development has been recently made near the top of the hill, having opened into some good ore which is now showing a width of four feet. The daily output of ore has been about 70 tons, which is easily handled by mill No. 2. The total shipments of bullion, on February account, amount to \$91,191.93. The production on March account, to the 8th inst., was \$10,782.75.

MOUNT DIABLO.—The intermediate drift, below the third level, and west of winze No. 1, is yielding several carloads of \$65 ore daily, from bunches in a large ledge of low grade ore.

JACK-RABBIT DISTRICT.

LOOKING WELL.—*Pioche Record*, March 10: The claims in Jackrabbit District are now looking better than they have at any previous period. The claim owners are all assiduously working their mines, and during the past two weeks ore has been uncovered in several claims.

TAYLOR DISTRICT.

NEW STRIKE.—*Eureka Sentinel*, March 10: A large body of high grade ore has been struck in the Monitor and Gore, in Taylor District, on the north side of the ravine, says the *Reflex*. Two drifts have been run just inside of the boundary lines of each claim, and both are in ore, top, sides and bottom. The drifts start from a point common to both, but diverge, one going into the Monitor ground and the other into the Gore. The new strike is well calculated to brace up mining property in Taylor District at a time when it does not stand particularly in need of it. Taylor is one of the few mining districts that is destined to come to the front on its own merit.

Arizona.

ITEMS.—*Tombstone Republican*, March 8: The Lima Con. is taking out good ore, and the lower levels look fine. The Vizina continues on the even tenor of its way, making its regular shipments of ore to the Boston mill. At the Emerald, work putting on a collar on the shaft is nearly completed, and sinking will begin in a day or two. The Sidney has resumed work, and will push its crosscut west to intersect the Grand Central west ledge in its south mine. The boilers are set for the pumping works at the Grand Central, and the stations and tanks for the pumps are nearly complete. They are now waiting on the machinists in San Francisco. The ore yield of the Ingersoll is more now than at any previous time in the history of the mine. The hoisting works enable them to handle the output to far better advantage than they could do with the whim which they used to develop the mine. The Prompter shaft is down 330 ft, with a crosscut 12 ft in the ledge, with better indications than heretofore. The next work will probably be a level run along the ledge to the west, toward the old shaft, when it is believed a large body of good ore will be developed.

Colorado.

WATTS.—*Georgetown Courier*, March 10: A force of 8 men have commenced operations on the Watts lode, near the Shively.

BRUCE & DAVIES have leased the Mammoth mine, on Sherman mountain. The mine contains large bodies of low grade ore, and small quantities of a high grade.

ORE.—Large bodies of ore have recently been encountered in the Donaldson mine. The mill is fast assuming shape, and a portion of it is under roof. The framework of the tramway from the mill to the mine is completed.

THE CALYPSO lode, which is situated on the log-back between Gray's Peak and McClellan mountain extending from the Horseshoe into West Argentine is owned by Mr. Hewitt and others. They propose building a trail to the Stevens ore house, to which place the ore will be packed, then hauled. The lode carries a large body of galena.

GRIFFITH.—That portion of the Griffith mine, formerly owned by the Wilson & Cass Co., consist-

ing of 700 ft, is now being worked by J. E. Johnson & Co. They are driving two levels from the north side of the shaft. The lower level is 170 ft deep from the mouth of the shaft, the other about 100 ft. There is a fine body of ore in the lower levels being from 8 inches to 3 ft in width. A trial lot of nine sacks was run and yielded \$53.90 net. It looks like old times to see the tramway in operation.

Idaho.

REPORTS FOR SALE.—*Wood River Times*, March 7: There is a report in circulation in town that the Mayflower, Jay Gould, Bullion and other mines are all sold to an English syndicate, which proposes to employ every miner they can get room for in actively developing the properties this summer. It is now over one month since the agents and experts sent here by the English syndicate left Wood River. They were thoroughly experienced gentlemen, and after carefully examining the mines some three weeks, were so favorably impressed with their value that it was asserted at the time that the sale would be concluded. The information now received is believed to be authentic, and this pending negotiation was the cause of the late inactivity of the mine managers at Bullion. The Mayflower and Jay Gould never showed so well as at present. The workings have recently opened very large bodies of high grade ore, and should the mines now change hands at the prices named, it is an assured fact that, instead of being worked hereafter for a sale, they will be worked for product and profit. This change of programme will be of the utmost advantage to Hailey and the entire Wood River country, in the employment of, as is estimated, 1,500 miners, and in increasing the bullion shipments to such an extent as to prove Wood River what all resident mining men are now quite well satisfied it is, to-wit: the most extensive, as well as profitable, region for mine investments in the United States.

FOUR STRIKES IN ONE DAY.—Not only was a body of high grade ore struck, yesterday, in the Jay Gould, but also in the lower workings of the Mayflower, and Bullion camp is greatly elated thereat.

SALE OF THE QUINBY HILL MINES.—Colonel Broadhead has negotiated in New York, to a syndicate, the Quinby Hill mines, which were owned by J. C. Anderson, of Eagle Rock, Col. Broadhead and others. The mines are 40 miles north from Hailey, on the mountain summit two and a half miles northeast of Galena, and are above the timber line. Considerable very rich ore has been extracted, and some shipments made last year to the Hailey sampling works prove it high grade. Work will be opened with ample capital.

THE Royal Gorge and the Silver Ledge mines have been worked all winter under the superintendence of Mr. J. B. Hewitt. The ore has been carefully stored away, and as soon as the snow leaves, there will be many tons ready of shipment. At the Royal Gorge there are over 100 tons that will run 150 ounces silver, 6% copper and 2 ounces gold. At the Silver Ledge are 400 tons of galena that will run from 60 to 160 ounces silver, and will average 50% lead. The Horse Shoe Co.'s tunnel has just reached the lode, which looks well, and the men who were at work were in high spirits over the outlook.

MENDOTA.—We learn the output of the Mendota mine of February, was 56 tons 640 lbs, the gross value of which was over \$4,500, and which netted nearly \$3,000. This was produced by Beck & Co., lessees, with the labor of less than four men employed in the mine. The lessees are preparing to add a night shift. Hennessy & Shay, adjoining lessees, are sinking a new shaft, in which they struck 18 inches of solid ore at a depth of 25 ft, which shows abundant gray copper, and the vein is widening as they go down. The shaft is to be sunk 60 ft before drifting is commenced, and it is highly probable they will have good ore all the way down.

Montana.

MONTANA COPPER CO.—*Butte Miner*, March 7: The Montana Copper Co., confines its works in the Colusa strictly to that point, where the copper ore contains an average of about 40 ounces of silver per ton. Sufficient ore is taken out, to supply the blast-furnace, and five matting furnaces. It requires the steady run of 8 calcining furnaces to calcine the ores, two more calcining furnaces are in process of construction and Mr. Raunheim expects to start them up this week. An enormous ore pile is roasting in open heaps, the latter still increasing. We counted 15 heaps and were informed that each contains from 40 to 50 tons of coarse ore. The first class ore from the mine is shipped separately, probably to England, same as the matte.

THE MOULTON.—The *Miner's* reporter took a trip through the Moulton yesterday and found the mine looking well in every level, stope and drift. The southwest and southeast drifts from the 300 west cross-cut are being vigorously driven. The southwest drift has advanced 40 ft on the ledge from the west cross-cut. The ledge is showing up fine and stands out 8 ft wide, all quartz. The southeast drift which was started last week, is in 10 ft. The vein is widening and looking well. An upraise has been started on the 300 north vein, and is in a fine body of ore which carries heavy wire silver. The west drift from the 400 continues in good ore and the old stopes of the 200 are producing their usual output. After a steady run of 65 days the mill has been shut down for general repairs since Friday, and will start up again to day.

Oregon.

NOTES.—*Jacksonville Times*, March 10: Jack Layton, of Applegate, has a large force of men at work cleaning out his ditches. Goldworthy & Justus, of Footh Creek, who have superior water privileges, are able to do considerable pipping. Sargent & Sons, who are mining on Thompson creek, Applegate precinct, have obtained excellent prospects. The weather continues discouraging to miners, who fear that they can make no run of any consequence this season. Bebec & Co. have been making a claim near Waldo, which turned out better than Supt. Hawkett expected. Some of the miners have not done any work at all so far. The present season is the worst for mining ever known in southern Oregon. Frank Ennis and James Hansen, accompanied by Charles Howard, surveyor, went over to Josephine county last week, to look at some mining ground which they will probably purchase. Mr. Ennis returned Tuesday.

"Rusty Gold."

The following paper on "The Cause of Rustiness, and of Some of the Losses in Working Gold" was read before the American Institute of Mining Engineers by T. Egleston, of the School of Mines, New York:

There has always been a theory among those working placer mines, that gold is both found "rusty," and becomes so under treatment, by which they mean, not that gold becomes coated with oxide of gold, but that it is either coated superficially or alloyed with some substance which prevents the contact with mercury, and thus precludes the possibility of amalgamation. To such conditions of the gold are ascribed the losses in working most placer deposits. Rusty gold is often talked about, but is not often shown, and when produced oftener amalgamates than not. It is frequently covered with a brownish coating, and has a much redder color than ordinary gold. The coating is very irregularly distributed over the surface, every spot where the least abrasion has occurred showing the true gold-yellow. All such spots form contact surfaces, and cause the whole piece to amalgamate readily. When the gold is wholly coated it resists the action of the mercury for a considerable time, and, perhaps, altogether. This coating on gold is due to the superficial action of some substance, which is soluble, and is often precipitated at the same time and by the same causes as the gold, for fine particles of gold are sometimes visible with the microscope in the detached coating. This coating has never, to my knowledge, been carefully analyzed. Those who describe it say that it often cracks off from pieces of gold, leaving them bright. Nuggets of some size are said to have been found in South America, in alluvial soil, coated with a silicate of iron containing considerable gold. Very often the film is entirely composed of silica, which is deposited on and beside the gold. This silica is sometimes opaque, and again quite transparent, so that the gold can be seen dissemiuated through it, with the microscope, just as chalcocite crystals are seen in the red chalcodony of the district around Knoxville, Cal. When the silica surrounds the gold entirely it prevents the gold from being attacked by the mercury, just as the fine particles of gold from the veins are carried off in the rock when it has not been rendered sufficiently fine in the crushing. While there are many

Artificial Causes Which Produce the Rustiness

Of gold, this covering of the surface with particles of some foreign substance is probably the only one which occurs in nature. In the separation of gold from its ore there are a number of causes which render it rusty or prevent its amalgamation in the mill. Some of these causes I have recently had occasion to investigate, and are, I believe, now announced for the first time; others have been more or less known for a number of years.

It has been asserted that the presence of certain substances alloyed with the gold would prevent its amalgamation. This I have generally found not to be the case. I have made a number of these alloys, and have found them to amalgamate without difficulty, but chemical combinations frequently do resist the action of the mercury altogether, or when they yield it is attended with the formation of a chemical compound with the mercury, and the consequent loss of the latter.

In order to ascertain the causes which prevent the amalgamation of gold, I undertook to reproduce artificially the conditions which were supposed to prevent it. These I found to be mechanical and chemical. I found that if a piece of soft gold which could be easily bent, and amalgamated readily, was hammered on a perfectly bright anvil, with a bright hammer, giving several rapid blows, until the gold had become hard and had acquired a certain amount of elasticity, it would remain in juxtaposition with mercury for a very long time without being affected by it. This hammering increases the density of the metal and closes the pores, so that I have recently had a piece of gold which was put into this condition by hammering remain nearly two weeks floating on mercury without being attacked. If the gold in this condition is heated and cooled slowly, it again amalgamates rapidly. If, however, it is cooled rapidly by plunging it suddenly into very cold water, the amalgamation takes place very slowly. The same metal, after being repeatedly rapidly cooled and heated, amalgamates more readily than if it has only been treated once.

To ascertain the

Effect of Different Substances on the Gold. A strip of clean gold which readily amalgamated was dipped into a solution of sulphhydrate of ammonia, and also into one of sulphuretted hydrogen. After being withdrawn from these liquids and allowed to dry, mercury would not touch either of the pieces. The effects of grease are well known, and the greatest care is taken in most mills to keep the "quick" bright, either by rubbing or by the addition of chemicals, to such an extent in some cases that the chemicals themselves used in excess are often a cause of the very thing they are intended to prevent. All these causes, the hammering, the effect of sulphuretted waters, and also the effect of grease, occur in every mill, and probably have something to do with the losses in gold which take place there.

The effect of the different elements likely to be found with gold was also investigated. A strip of gold which would amalgamate easily

was exposed to vapors of sulphur, after which it would not amalgamate. When the piece was heated in the flame of a Bunsen burner, the film of sulphide was decomposed, and the gold amalgamated readily. To test the effects of arsenic and antimony upon gold, these metals, in variable proportions, were melted with it, and it was ascertained that considerable quantities of arsenic and antimony were in the alloys. Both these alloys amalgamate very easily. Gold and arsenic and gold and antimony were then precipitated together, and it was found that the precipitates were compounds of antimony and gold and of arsenic and gold; they also amalgamated readily. It has been asserted that .0004 gram of antimony to the ton of auriferous pyrites of Grass Valley, and .001 gram in that of Callao, was sufficient to prevent the amalgamation of the gold. This seems, however, to be not quite exact, if the statement given of the conditions in which the gold is found be correct, for there does not seem to be any reason why an alloy with a much larger amount, as in the artificial compounds, should amalgamate readily, and the natural one containing so much less, refuse to do so.

The Effect of Sulphur

Was further studied by making a regular sul-

phur has doubtless the effect to make some of the particles of gold wholly unattainable by mercury, while the action of rubbing that occurs in the arastra is much more likely to pulverize the fine particles of pyrites, to break up any coating that may be around the particles of gold, and to rub off any superficial deposit, and thus bring the gold into contact with the mercury and make it amalgamate. It would be folly to advocate the reintroduction of the arastra, which is so limited in its output, but I am satisfied that we shall have to come back to its principle. It is a very remarkable fact that when, in the early days, Mexicans with the arastra got \$50 to \$60 a day, the stamp mill working on the same rock obtained only \$15 to \$20, and instances are cited where, with the best modern machinery, only \$20 to \$30 can be got out of rock which yields \$700 to \$800 by the fire assay. One or two machines have recently been constructed on the arastra principle, but no systematic tests have been made of them, and little done beyond the singing of their praises by enthusiastic inventors.

The Most Delicate Scales.—What is claimed

to be the most delicate pair of scales in the world,

A BEE RANCH IN VENTURA COUNTY.

phide of gold. When this was heated, it was found that the sulphur was readily driven off by ignition, and the residue, which was bright yellow gold of exactly the same shape as the sulphide, easily amalgamated. A phosphide of gold was then made by pouring melted phosphorus upon hot sponge-gold, and expelling the excess of phosphorus by heating for some time in a non-oxidizing atmosphere. It did not amalgamate. Oxide of gold was made, but this compound is so very unstable, and so readily reduced to metallic gold by simply rubbing, that it could not possibly have any effect on preventing amalgamation, although it is not attacked by mercury. An amalgam of gold was then placed in acid, which easily dissolved out the mercury, and left behind a brown crystalline residue of gold, which readily took up mercury again.

It will thus be seen that

The Stamp Mill

Is not a rationally designed machine. The action of pounding is likely to put some of the gold into such a condition that the mercury will not touch it, and to flour the gold, as well as the quicksilver. There is, besides, in the mill every probability of the introduction of grease or greasy substances, like the powdered hydrated silicates of magnesia and of alumina, which not only froth but coat the gold with a slime which prevents the action of the mercury. If the water used in the mill is not pure, there is a further likelihood of the introduction of sulphuretted hydrogen, and of other soluble sulphides, which act superficially on the small particles of gold, and prevent the action of the mercury. The pounding action of the stamp

according to the account given in the scientific papers, the beam is made of rye straw, and together with the pans, which are made of aluminum, weigh only fifteen grains. In the most delicate scale heretofore made the beam and pans weighed 68 grains—the beam being made of aluminum—and the instrument was capable of weighing to the one-thousandth of a grain. This new scale, however, weighs to the one-tenth-thousandth of a grain. A piece of hair one inch long, on being weighed with this wonderful apparatus, was found to represent the almost infinitesimal quantity of one-thousandth of a grain.

California Bee Ranches.

The engraving shows a bee ranch in Ventura county, and presents many features common to the bee farms of Southern California. They are generally little nooks of land near the mountains, which give acres of natural bloom, from which the bees gather their stores. They are quiet retreats, where solitude is rarely broken, save by the monotone of the busy insects or the ripple of the mountain stream which flows by the apiary. The picture shows the arrangements common to the practice of bee-keeping on these farms, of which there are hundreds in the counties of San Diego, San Bernardino, Los Angeles, Ventura and Santa Barbara. In a good year, when sufficient rain brings a full growth of the natural bee forage plants, the gathering of honey surpasses bee work in any other county where bees are kept, and brings abundance of money to the patient apiarian.

Building Debris Dams.

Another Decision Against the Farmers.

In the Superior Court of Sacramento county, last week, Judge T. B. McFarland rendered his decision in the case of Digory Hobbs vs. the Amador and Sacramento Canal Company et al., on a motion to vacate or modify an injunction previously granted against defendants as a hydraulic mining company from tailing into the tributaries of Cosumnes river. Freeman and Bates appeared in behalf of defendants for the motion; Geo. Cadwalader for plaintiff in resistance. The decision is as follows:

In this case there has been submitted a motion to dissolve or modify the temporary injunction hereinbefore issued.

The main defendant is a corporation. It was organized, as alleged in the complaint, "for the purpose of constructing ditches and carrying water in the same to mines, and disposing of the same, and mining therewith." It also appears from the complaint and affidavits on file that defendant for many years has had a ditch running from the headwaters of the Cosumnes river to a place called Hill Top, in which it had continuously conveyed water to said last named place; that at said Hill Top defendant owns mines which it has for many years continuously worked with said water, and that it has also sold water to others to be used in mining at said place. It does not appear that the defendant has been, or is, engaged in mining, or selling water for mining, at any other place. Hill Top is at the head of Cook's gulch, which empties into the Cosumnes river at Cook's Bar. The injunction restrains defendant from dumping any tailings into Cook's gulch, or into the Cosumnes river, and from selling water to the owner of any mine, the tailings from which would flow into said gulch or river. The injunction was granted without notice.

Counsel for defendant very forcibly argues that under these circumstances the injunction must be totally dissolved, because without notice it suspends the "general and ordinary business of a corporation." Generally a temporary injunction may be granted either before or after notice; but Section 531 of the Code of Civil Procedure provides that: "An injunction to suspend the general and ordinary business of a corporation cannot be granted except by the Court, or a Judge thereof; nor can it be granted without due notice of the application therefor to the proper officers, or managing agent of the corporation, except when the people of the State are a party to the proceedings." Although this provision has always been a part of the statutory law of California, and similar provision has existed in New York for many years, I find no judicial interpretation of it in either State; and my attention has not been called to any case in point elsewhere.

It may be reasonably mooted whether this provision refers to the stopping of the corporation—to the suspension of its corporate functions, the temporary paralyzing of its corporate life, or whether it refers to those acts—to that kind of business—which a natural person may do as well as a corporation; and if to the latter, then what constitutes such a total suspension as would come within the provision? If the question were submitted to me upon an original application for an injunction, I would be less embarrassed in determining it. The conclusion to which I have come is this: While I have doubts as to the power to grant the injunction in this case without notice, I am not so clear about the matter as to feel warranted in declaring it void from the beginning, which would be the result of sustaining defendant on this point. And I have alluded to the question to this extent, so that the Bar may consider it in future cases.

The motion to dissolve or modify this injunction involves, in some measure, though not wholly, the general question of the right of hydraulic miners to continue their business. Upon that general question, with the exception of a case recently decided by this court, there are no authorities in point, and no precedents to follow. As no other country ever presented such a spectacle as the present conflict between the miners and a part of the agricultural interests of California, so have the courts of no other country been called upon to determine such a question as that conflict raises. But while neither the Supreme Court of this State, nor any of the Federal Courts, have had occasion yet to pass upon the question, it has been determined, to some extent at least, by a recent decision of this Court, Judge Temple presiding. I refer to what is generally known as the Gold Run case. That case was elaborately prepared and presented. A great many witnesses—scientific and otherwise—from all parts of the country, were examined. Each side was represented by able counsel. The judge before whom it was tried was eminent in his profession, and of wide experience on both the nisi prius and Supreme bench. I think, therefore, that, in the present unsettled state of the laws, I may safely follow his conclusions, so far as they apply to this case.

From a careful reading of his findings and opinion I take his conclusion to be this: That hydraulic miners have not the right to continue to indiscriminately flow all the tailings from their mines into the streams, to the injury of riparian owners below; but that they may continue to mine provided that, by any means, they can and do retain all the heavy material and allow nothing to escape except the light matter which is held in suspension in the water. The learned Judge says: "I have concluded to so find that

when the heavier debris is completely impounded mining may be resumed, virtually refusing to hold that the plaintiff may enjoin such operations as only corrupt the water with mud and render it less suitable for domestic and other uses. Perhaps I am somewhat moved to this by the consideration that otherwise mining can never be prosecuted at all. It will probably be impracticable to impound the lighter portion of the sediment. I confess I shrink from a consequence so far-reaching."

In some respects the case at bar materially differs from the Gold Run case. In the latter the State was plaintiff and represented, or assumed to represent, all the people, and all the interests injured by mining. It involved questions not only of damage to agricultural lands, but of damage to navigable rivers and the bay of San Francisco. The case at bar is between individuals, and involves only damage to the private land of plaintiff.

Again, the facts of this case differ materially from those of the Gold Run case. The motion was submitted upon affidavits. These were conflicting, contradictory and unsatisfactory. Both parties requested me to visit the premises and make a personal inspection of the mines, the gulch, the dams and all the surroundings. This I did a few days since, and my conclusions of facts are founded on both the affidavits and my personal examination.

The hydraulic miners of the upper Sierras used to piping against banks several hundred feet high, with a corresponding hydraulic pressure, would hardly call these diggings at the Hill Top hydraulic mines at all. They are situated on the lowest part of the foothills, and are composed of small hills or hillocks surrounding the upper part of Cook's gulch. The gravel deposit ranges in height from 12 to 30 or 35 feet. The average height is certainly much less than 30 feet. The vertical hydraulic pressure is from 25 to 30 feet. The water, therefore, comes from the nozzles with very little force to bore into or knock down the banks. The process is more like washing or sluicing than piping. It is aided by occasional blasting with powder; but still the amount of material washed off is necessarily small. The bank is of a reddish color, and is composed of cobbles, smaller gravel stones, clay, and some sand. The tailings from the mine, except the very heaviest, run through a cut and flume and dump into Cook's gulch. About 2,000 feet below the dump there is a brush dam entirely across the gulch. It is about 500 feet long, and, when I saw it a few days since, about nine feet high. It seems to be very firm and strong. It has been raised gradually as the tailings have accumulated above it. When I saw it there was a solid mass of tailings above it to within a foot or two of the top. Some distance above this dam the water spreads out in several channels, which continually change and seem to deposit nearly all the heavy material. This dam is not intended to be water-tight, but to catch the tailings and allow the water to find its way through the upper part of brush. From a point 300 or 400 feet above the dam, up to the dump, the gulch is somewhat steep, but below the dam the grade is very light, and the surface quite flat. At a point 2,270 feet below, defendant has constructed another dam, which is made of timbers and earth, and is water-tight. This dam hacks the water so as to make a pond 300 feet wide, and several hundred feet long. It could easily be made wider and higher. Attached to this dam, by a flood-gate, is a board flume, which carries the waters to a point about 300 feet from the river, where they are again dumped into the gulch. Nothing seems to pass into the river except such light material as is carried in suspension. Heavy matter, in order to get into the river, would have first to pass over at least 1,500 feet of surface before it reached the tailings held back by the brush dam. It would then have to be carried over the level surface of such tailings and through the dam, which is not likely to happen. It would then have to pass over a nearly level surface for about 1,800 feet, and then through a pond of water 400 or 500 feet, and up over the flood-gate of the lower dam. Such an occurrence is scarcely possible, certainly not probable. All this, however, is upon the basis that defendant, either by enlarging the present dams as necessity may require, or by building additional ones, shall keep the gulch up to its present capacity of holding tailings, which will be its duty to do. Between the present dams there is room for erecting several others. The average width of the gulch between these dams is at least 500 feet; and I see no difficulty, with proper care and diligence, in retaining the heavy material for a long time to come—perhaps until the mines shall have been exhausted.

But it is claimed by plaintiff that the dams are liable to break, and suddenly precipitate upon the lands below the accumulated mass of tailings. Of course, any dam may break; although it is evident that a dam filled nearly to the top with solid earth has to bear no such pressure as a dam of similar height filled with water. Whatever might be this danger in large rivers swept in flood times by torrents gathered from drainage areas of hundreds of thousands of acres, I think that the apprehended danger in this case has no reasonable foundation. The drainage area of Cook's gulch is of the most limited character. Its entire length from the Cosumnes river to the uppermost point from which rain water could naturally flow into it is only one mile and a half. From the present brush dam to the upper end of the gulch is only three quarters of a mile. The average width of the level part is from 400 to 500 feet, and the dis-

tance from either side to the top of the hill is very short. I do not think that the average distance from the top of the hill on the other side is greater than three fourths of a mile. It is evident, therefore, that no considerable amount of natural water—certainly no dangerous torrent—is ever likely to flow down said gulch. If the dams should break, the only danger would be from the water flowing from defendant's ditch—the amount being more than 1,000 inches. But in case of danger the defendant could immediately turn the entire water of the ditch off and away from Cook's gulch, and it would be both its duty and interest to do so. Considering these circumstances and the further fact that plaintiff's land is more than 16 miles below the mouth of the gulch, I see no just cause for plaintiff's fear of injury from the breaking of the dams.

If the Courts of last resort shall declare the law to be that the miner has no right to pollute the streams at all, then, of course, defendant will have to be perpetually enjoined from working its mines. But, assuming the present state of the law upon the subject to be as I have stated it, and as it was declared in the Gold Run case, then I think that the injunction should be so modified as to allow defendant to work its mines in accordance with the views and upon the conditions herein set forth. Of course this decision is based upon the particular facts of this case, and is not to be considered a precedent for cases where the facts are materially different.

An order will be prepared and entered modifying the injunction in accordance with these views; and defendant must exercise the greatest diligence in keeping its dam up to its present efficiency, or the modified injunction will be considered as violated.

USEFUL INFORMATION.

Useful Facts in Hydraulics.

Doubling the diameter of a pipe increases the capacity four times.

The ordinary speed to run a pump is 100 feet of piston per minute.

To find the area of a piston, square the diameter and multiply by .7854.

Each nominal horse power of boilers requires one cubic foot of water per hour.

A gallon of water (U. S. standard) weighs eight and one third pounds, and contains 231 cubic inches.

A cubic foot of water weighs 62½ pounds, and contains 1,728 cubic inches, or seven and one half gallons.

Circular apertures are most effective for discharging water, since they have less frictional surface for the same area.

The capacity of pipes is as the square of their diameters; thus, doubling the diameter of a pipe increases its capacity four times.

Hydraulics treats of fluids in motion, and especially of water, the machinery and works for raising and conducting it, its action in canals, races and rivers, its adaptation to water wheels as prime movers, etc.

The height of a column of fresh water, equal to a pressure of one pound per square inch, is 2.31 feet. (In usual computation this is taken at two feet, thus allowing for ordinary friction.)

To find the velocity in feet per minute necessary to discharge a given volume of water in a given time, multiply the number of cubic feet of water by 144, and divide the product by the area of the pipe in inches.

To find the pressure in pounds per square inch of a column of water, multiply the height of the column in feet by .424. (Approximately every foot of elevation is considered equal to one-half pound pressure per square inch.)

To find the diameter of a pump cylinder to move a given quantity of water per minute (100 feet of piston being the speed), divide the number of gallons by four, then extract the square root, and the result will be the diameter in inches.

The time occupied in discharging equal quantities of water under equal heads, through pipes of equal lengths, will be different for varying forms, and proportionally as follows: For a straight line, 90; for a true curve, 100, and for a right angle, 140.

To find the horse power necessary to elevate water to a given height, multiply the total weight of column of water in pounds by the velocity per minute in feet, and divide the product by 33,000 (an allowance of 25 per cent. should be added for friction, etc.).

To find the area of a required pipe, the volume and velocity of water being given, multiply the number of cubic feet of water by 144, and divide the product by the velocity in feet per minute. The area being found, it is easy to get the diameter of pipe necessary.

To find the quantity of water elevated in one minute, running at 100 feet of piston per minute: Square the diameter of water cylinder in inches and multiply by four. Example: The capacity of a five-inch cylinder is desired. The square of the diameter (five inches) is 25, which, multiplied by four, gives 100, which is the number of gallons per minute (approximately.)

The best form of aperture, for giving the greatest flow of water, is a conical aperture, whose greater base is the aperture, the height or length of the action of cone being half the diameter of aperture, and the area of the small opening to the area of the large opening is 10 to 16; there will be no contraction of the vein, and

consequently the greatest attainable discharge will be the result.

Water in falling is actuated by the same law as other falling bodies; passing through one foot in one fourth of a second, four feet in one half second, nine feet in three fourths of a second, and so on; hence its velocity flowing through an aperture in the side of a reservoir, bulkhead or any vessel, is the same as that of a heavy body falling freely from a height equal to the distance between the middle of the aperture or hole to the surface of water below.

WATER A PRESERVATIVE OF TIMBER.—The posts of a railing recently put up in the new office of the Sycamore Powder company, on Market street, Nashville, are carved out of white oak timber cut about 45 years ago, at Sycamore Mills, in Cheatham county, Tenn. The timber out of which these posts were made was used by the late Judge Samuel Watson in the construction of a mill-race, and lay immersed in the water over 42 years, when they were taken out, and after being seasoned, Major Eugene Lewis, Manager of the Powder Company, had them fashioned into their present shape. The wood is as sound as it was the day it was cut, and has become as hard as iron, and turned very dark, almost black color.—*Southern Lumberman.*

TO REMOVE GLASS STOPPERS.—When, says Dr. Squibb, the fixed stopper of a glass bottle resists all management—such as warming the neck with a cloth wet with warm water, by tapping and by the wrench, or by all these in combination—there is another means which will almost always succeed. Let the bottle be inverted, so as to stand on the stopper in a vessel of water so filled that the water reaches up to the shoulder of the bottle, but not to the label. Two or three nights of this treatment may be required sometimes before the stopper will yield.

A SINGULAR OCCURRENCE.—Seven large grindstones burst in the Junction Iron Company's nail mill, recently, at Mingo Junction, Ohio, one at a time. The reports were about one minute apart. Captain James Prentiss, of Steubenville, was seriously hurt, and will die. About 200 men were in the building, and it is remarkable that more were not killed or injured.

GOOD HEALTH.

An Improved Earth Closet

EDITORS PRESS:—In *Rural Press* of Mar. 3d, one of its correspondents gives some advice concerning an earth closet, and how to construct one on an inexpensive plan. We have had one in use which has proved eminently satisfactory for ten years, or more, and can heartily recommend the earth closet plan to all as a vast improvement over those pest-breeding abominations, the usual privy vault, whether deep or shallow (for there is little difference between them in a hygienic point of view), wherein the seeds of disease lie in wait, like assassins in the dark, ready to seize upon the unwary at any moment, when, from weakness, over-exertion, or a receptive condition of the system from any other cause, they may find an unsuspected and unguarded victim whereon to fasten their fatal fangs.

Our earth closet, though as simple in its construction as that recommended by your correspondent, has some improvements over the one there described, which, we think, add greatly to its convenience, as they contribute materially to the ease and rapidity with which its contents can be disposed of whenever that operation becomes necessary. It consists of a plain wooden box, made of inch and a half lumber, one foot deep, six feet long, and eighteen inches wide, which is fitted under the ordinary outhouse; but, instead of being set flat upon the ground, the box is arranged upon short 2x4 runners, like a sled, with a heavy staple (or a hole bored by a large auger will answer just as well) in the end of each runner. Into these, a rope or hook can be fastened, by which the box can be hauled out without any trouble to the manure pile, where, by the aid of two strong handles attached to each upright end of the box, the contents can be dumped at once in any desired spot, without the necessity of further handling, and the box washed out with the hose, sprinkled with lime, or a solution of copperas water, as a deodorizer and disinfectant, and restored to its position under the outhouse in as healthful and unobnoxious a condition as it was when it was first placed there.

Wherever it is practicable, it adds greatly to the convenience of this matter if the outhouse itself forms a portion of the barn-yard fence, with the back toward that yard. A broad plank hung by strong hinges forms a hanging door, which hides the movable box from sight, except when it is to be emptied, when the trap-door is easily fastened up and out of the way until that operation is completed, when it falls into place again.

During the summer months, when road dust, as a dry, fine powder, can be obtained in any quantity, it should be gathered up and stored away in barrels in some out of the way place where it will be protected from the weather. From there it can be transferred as it is required to a vessel kept in the earth closet for that purpose, and used to sprinkle over the contents of the box whenever necessary. This will

completely destroy any disagreeable odors arising therefrom, and in a marvelously short time convert the whole mass into clean earth.

It is a good plan to have the emptying of the box as a signal for turning over the manure pile, dumping its contents in the desired place, and heaping upon them the fresh litter from the barn and sheds, then transferring upon this pile that under which the last deposit from the box had been buried. In this way the whole heap is thoroughly worked over every little while, and the night soil (which the previous admixture of clean earth had disinfected of all its dangerous disease-breeding elements) becomes a power for good instead of evil, since its presence, when thoroughly incorporated with other manures, greatly enhances the value of the whole mass.

Realizing how important to the health of whole communities is the question of the proper disposition of deposits of this nature, we have been more explicit than was, perhaps, necessary in our description of this cheap earth closet, with the hope that others may be induced to adopt this plan, and thereby render innocuous a source of disease and danger as universal as it is unsuspected.

HARRY LYNWOOD.

BREATHE THROUGH THE NOSE.—Dr. Ward, Physician to the Metropolitan Throat Hospital New York, in an article on singers' throat troubles, in the *Musical Critic*, treats of the various kinds of catarrhal troubles experienced by public singers, and repeats the well known fact that the nose is the only channel through which air should pass during ordinary act of breathing, the mouth being intended only as an accessory breathing agent when, on certain occasions—as, for instance, running—the lungs demand a rapid supply of air. The air, in passing through the nostrils, is warmed and sifted of its harmful ingredients, and thus prepared for its reception into the delicate structures below. If it passes directly into the mouth without the above preparation, it will frequently cause irritation and inflammation of the mucous membrane lining the mouth and throat by being, in the first place, too cold, and in the second place, by containing irritating particles of dust and other matter.

SERIOUS HURTS THAT FAIL TO KILL.—A short time ago a shoemaker of Astoria, N. Y. shot himself twice with a heavy pistol, once in the ear and once in the month. He was brought to the Roosevelt Hospital, in this city, where it was discovered that the first ball glanced from the skull. The other is thought to be somewhere in the head, perhaps in the brain. Speedy death was expected; but the next day the patient walked away from the hospital, saying that he was sorry for the attempt on his life, but appeared to be in no immediate danger of dying.

With this case as a text, a writer in a morning paper reviews a large number of more or less marvelous cases of recovery from grievous hurts, showing that serious injuries to the main organs of the body are not always followed by death. Men persist in living, not only with bullets in their brain, holes in their stomach, dislocated vertebrae, and wounds in the heart, but even with open wounds clear through the body. During the civil war, General H. A. Barham, of Brooklyn, received in battle a wound which still remains an open passage through the body. For years the treatment of this wound has been simply to wear in it a roll of prepared lint, which is renewed daily. The suppuration of the wound is constant though variable.

General Shields, of Missouri, had a similar wound extending through his body, and open in front and behind. His wound, it is said, was received in the Mexican war, and he wore, not lint, but a silk handkerchief in it. This he could draw directly through his body.—*Sci American.*

THE DIGESTIBILITY OF OYSTERS.—Why oysters should be eaten raw is explained by Dr. William Roberts in his lecture on "Digestion." He says that the general practice of eating the oyster raw is evidence that the popular judgment upon matters of diet is usually trustworthy. The fawn-colored mass, which is the delicious portion of the fish, is its liver, and is simply a mass of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the hepatic diastase. The mere crushing of the oyster between the teeth brings these two bodies together, and the glycogen is at once digested without any other help than the diastase. The raw, or merely warmed oyster, is self-digestive. But the advantage of this provision is wholly lost by cooking, for the heat immediately destroys the associated ferment, and a cooked oyster has to be digested, like any other food, by the eater's own digestive powers. "My dear sir, do you want to ruin your digestion?" asked Prof. Houghton, of Trinity College, one day of a friend who had ordered brandy and water with his oysters in a Dublin restaurant. Then he sent for a glass of brandy and a glass of Guinness's XX, and put an oyster in each. In a very short time there lay in the bottom of the glass of brandy a tough, leathery substance resembling the finger of a kid glove, while in the porter there was hardly a trace of the oyster to be found.

MINERS and stage drivers are arriving in Salt Lake daily from Idaho with frozen hands and feet, caused by the severe weather of a few weeks ago. They are taken to the hospital, where amputation is found necessary in almost every instance.

Passing Events.

We publish this week a double edition of the MINING AND SCIENTIFIC PRESS, devoted to the description of the British Columbia mining regions. The large map we give will also be found useful for reference.

With the warmer weather, we hear of prospectors getting ready to start out in all directions, and within a few weeks many hundreds of them will be at work. Southeastern Nevada, a region which we recently described pretty fully, seems to be attracting a good many prospectors and miners about this time. The railroad facilities afforded will help the region out greatly.

The miners generally seem to have made up their minds to a dry season. In some directions, however, this is beneficial. River mining, for instance, has been prosecuted this year more favorably than ever before. This branch of business is however mainly carried on by Chinese, though some white men are at work. Along the river the unusually low stage of water has stimulated them to greater activity than ever before, this making it possible for them to work ground that would be inaccessible in ordinary seasons.

Our State Legislature has finished its labors and adjourned sine die.

Bodies of good ore are being developed in the Rescue, Stafford, and Original Hidden Treasure mines, at Hamilton, Nev., which are the property of the Sweetwater Co. The Elberhardt tunnel is also said to be looking well.

British Columbia as a Field for the Prospector.

As compared with California and most other sections of the Pacific coast, the prospector will find British Columbia a hard country in which to prosecute his laborious calling. In the first place, he has to penetrate the heavy timber belt, which reaches inland a hundred miles or more from the coast. If he proceeds, however, by way of the Fraser river, this is accomplished readily by taking the steamer at Victoria, which conveys him up that stream to Fort Yale or Hope, according to the stage of water. This carries him nearly through the heavy timber belt and to the edge of a more open country, which, as he proceeds further north or east, rises into a sort of elevated plateau sparsely timbered with pines and other coniferous trees, intermixed in some places with a rather stunted species of oak.

The forests nearer the coast, which consist mainly of spruce, fir and hemlock, stand tall and thick, forming a damp and gloomy stretch of woods without prairie lands or other openings, except occasionally a little glade at the confluence of the larger streams or a fern-clad hill, which seen afar off has much the appearance of a green meadow or a field of ripening grain. But it is all an illusion, these patches of "brake" serving no useful purpose except as a covert for rabbits and other small game. Though always green no animal ever feeds on this fern, nor do

hours continuance, there being no protracted storms. Even in the winter the snowfall here, except on the mountains, is not great, cattle subsisting in the valleys without housing or fodder. The streams abound with salmon and other fine fish and there is considerable game in this section of country. The miner can also obtain fresh beef and other supplies till he gets as far north as Caribeean and as far east as Hamloops and perhaps a little further. Beyond these points he will have to depend on fish, game and such provisions as he takes with him.

The most inviting portion of British Columbia to the prospector would seem to be over on Peace river and the region adjacent, gold in paying quantities having been found at various points along that stream. For several years past, small companies of Chinamen are reported to have been at work there. That they have made at least moderately good wages may be inferred from the fact of their remaining so long. Some parties of white miners operating on Cherry creek, and on several other streams in the Kootenay country, are also said to be doing tolerably well, and as there is now steamboat and railroad transportation well on towards that section of the Province, prospectors bound for the north might perhaps find there a good field for prosecuting their calling.

Fisheries and Lumber Interests of British Columbia.

The Fisheries.

In addition to the descriptive article accompanying the map, we are indebted to Mr. W. D. Patterson for the following notes: The salmon on the Fraser river are of two varieties.

OFF ON A PROSPECTING TRIP.

any except these mentioned ever frequent it. Not a blade of grass, or even a weed or flower is ever seen amongst it, its presence like a deadly Upas appearing to extinguish every other form of vegetable life. Although a great deal of the country occupied by these forests is but little elevated above sea level, much of it consists of scraggy hills and rugged mountains, portions of the latter being but scantily timbered. It is uninhabited, except a few white settlements along the Fraser, and the aboriginal tribes, who gather in lodges near the coast and along the principal streams. As it affords but little grass or other sustenance for animals, this region contains scarcely any deer, or other large game. It abounds, however, with herries, on which some bears manage to live, and which, in connection with salmon, form the principal food of the Indians. No gold or silver mines of importance have been found in this heavily timbered section of the country. It behooves the prospector, therefore, to get through it as speedily as possible into the more pleasant and open regions beyond.

But even here the seeker after gold will have such difficulties to encounter and such hardships to undergo as will try his courage and powers of endurance severely. Owing to the rigors of the winters no mines can be worked nor prospecting done during that season of the year, the first of April being as early as the miner can safely take the field, which can be kept never later than the end of November. Never more than eight, usually not more than seven months of effective work can be counted upon in the course of the year. The climate in the interior of British Columbia from April to November may be considered a pleasant one, the summer months being warm with cool nights, as in California. Rain occurs during this period in showers usually of only a few

The sockeye, or early spring salmon, seldom weigh more than 10 pounds, and are generally much smaller, but they are a very fine fish, being of a blood-red color when opened, and very fat. This species run up the Fraser in the month of May, and the numerous canneries are then fully employed in netting and securing them. This run continues for about six weeks. The fall run of salmon commences in September, and the fish are of a different variety. They are called Cohoes, are very large and fat, and average from 15 to 20 pounds; some have been caught 50 pounds in weight, in 1881. The quantity of fish entering the river was so great that only the best parts of the fish were put up, and in many instances tons of fish were thrown away. This practice has now been put a stop to, and the canneries are only allowed to catch as many as they can put up.

Previous to the run of salmon in the spring, a small fish called the oilchian swarms in the river. They are of the size of sardines, of a rich and delicate flavor; and, when the fish is dried, so great is the quantity of oil contained in them, that, by lighting one end, they will burn like a candle. The Indians use them as such. The oil extracted from them has been shipped to London in large quantities, and has been found to be superior to cod liver oil for medicinal purposes. Sturgeon are also caught, of large size and good quality, and other salt water fish, as halibut and cod, are numerous. The many other rivers along the coast are well stocked with fish, among which may be mentioned the stickle, naas, skeena, dean, hellacoola, homatheo, mimkish, and numerous others of smaller size; in fact, at the head of all the great inlets, some of which run inland from 60 to 80 miles in length, large rivers enter the sea. These inlets are of great depth, showing 100 to 200 fathoms, although they do not average over half a mile wide. They have been formed, no doubt, by the convulsions of nature during the tertiary era. Ships which have gone up some of these inlets have always made fast to shore. Some canneries are in operation on the Skeena and Naas rivers.

The Lumber Interests.

The saw mills in operation in British Columbia are mostly situated at Burrards inlet. Two

large companies, named the Moodie Saw Mill Co., and the Hastings Saw Mill Co., manufacture millions of feet of lumber for shipment to Australia and South America, and some other small mills are in operation. The logging camps have mostly cut the timber, for the mills along the salt water, called *Pinus Douglasii*. Large quantities of this timber cover the mountain sides, but of course the expenses of supplying the mills with logs will increase when logging roads have to be made to get the timber out to the sea board. The timber at a little distance back from the coast is the best. The cedar found along the river bottoms back from the shore line is very good, it is mostly red cedar and excellent for shingles and fencing. As we travel north the pine disappears and is replaced by the white spruce and white cedar. Above the parallel of 52° north latitude the pine almost completely disappears and the spruce is abundant. This is a very large tree and in good situation straight and without knots, makes tough, light lumber and works well for house use under the plane. Above the parallel of 53° the white cedar abounds. This is a splendid wood, tough and close in the grain and works well under the plane. It is said that the *Teredo Navalis* will not bore in it. It is therefore a most useful timber for wharf piles. For ship building it has been decided by ship builders to be an excellent wood and in lasting qualities it equals the best oak. The beautiful arbutus tree grows on the south end of Vancouver's island and on the islands on the Gulf of Georgia. Hemlock everywhere abounds, some of large size; this is a coarse timber and makes rough lumber, but its bark is the best known in British Columbia for tanning purposes.

The Soil

Of British Columbia where cultivated has turned out good crops. The mean amount of rainfall, averaging 50 inches, annually causes the land on the coast to be more suitable for hay and root crops. In the interior lands of the region, on which the mean annual rainfall amounts to 25 inches, the soil is more alkaline in character, and therefore better suited for wheat crops. The rolling hills of the interior, covered with bunch grass, furnish excellent pasturage for thousands of head of horned cattle and sheep.

The Winters

Are not very long. The cold sets in about the 1st of December, and spring opens out about the 20th of March. The average depth of snow amount to about nine inches on the level. The coldest spell of the season is from the 25th of January until the end of February. In the north part of British Columbia the snow lies deeper and cattle do not thrive so well.

Regarding the mining interests, remark that the principal auriferous deposits have been found in the streams running from the Rocky mountains and spurs therefrom. Streams heading in the Cascade or Coast range have never proved very auriferous. Rich lodes of minerals have been found along the west flank of the Rocky mountains and there is no doubt when the country is properly prospected, it will prove to be a rich mineral country. The volcanic overflow of the tertiary period may have been the cause of the capping of the lodes in the subadjacent formations through the central portion of B. C. and on the coast, so that the river deposits are not rich in gold dust and other minerals. As we travel towards the Rocky mountains, the effects of volcanic overflows seem gradually to be less apparent and the metamorphic formations crop out. This is no doubt the reason of the streams being more auriferous.

The railroad will be completed in a few years from Port Moody on the coast to the Rocky mountains, so that mining machinery can be easily got into the interior and bullion shipped out, and I feel no doubt a large mining field will then be discovered along the west flanks of the Rocky mountains.

The Owyhee mines, according to the *Avalanche*, produced from 1865 to 1875 as follows: Oro Fino, \$2,756,000; Morning Star, \$1,200,000; Poorman, \$4,000,000; Golden Chariot, \$3,000,000; Ida Elmore, \$2,000,000; Red Jacket, \$3,000,000; Silver Cord, \$500,000; Owyhee, \$150,000; Mahogany, \$1,200,000; War Eagle, \$900,000; Empire State, \$160,000; Belle Peck, \$200,000; Trook & Jennings, \$150,000; Silver Legion, \$100,000. Add to this \$540,000 for other mines. This makes \$17,756,000 produced in Owyhee county from 1865 to 1883.

GETTING THAWED OUT.—From all parts of the country south and west of this point comes the encouraging news that the miners and prospectors are getting ready for the season's work. The country is becoming more populous, and claims which were abandoned are receiving a close scrutinizing. The companies which were nearly dead are waking up with the warmer weather, and everything points to the near development of just as good mines as were found in bygone days.—*Candelaria True Fissure*.

A ROPE of refined cast-steel has just been sent by the Roebellings from their mills in Trenton to San Francisco. It is 50,440 feet long, and its diameter is one inch and a quarter, and it weighs 51,000 pounds. It was put in two box cars, each open at one end, half the rope in one car and half in the other, in continuous coil. The rope is for a cable road.

The Patio Process.

The Method as Practiced in San Dimas.

The following paper by Richard E. Chism, San Dimas, Durango, Mexico, was read at the Colorado meeting of the American Institute of Mining Engineers:

San Dimas, in the State of Durango, Mexico, on the frontier of the State of Sinaloa, is the center of an extensive and rich mining region, which has been exploited for over a hundred years, and the patio process for working silver ores has there attained the highest perfection of which it is capable. Local modifications have been engrafted upon the underlying principles of the process, but, as a whole, the San Dimas practice so fully illustrates its typical capabilities, that I have undertaken to describe its workings in the hope of lightening, in some degree, the labors of my professional brethren who may have occasion to visit Mexico.

As is tolerably well known, the patio process,

called *caliche*, and feldspathic ores are called *metal calichoso*. An ore with much gangue is called *despoblado*. *Quimazon* is a black, porous kind of decomposed ore that looks like cinders. The first and second-class ores of the size above indicated are called *metal gabbaro*; smalls, or fine ore, are called *metal granza*.

3. Third class (*metal granza de linaque*, or *tierras de linaque*.) This class comprises the smalls from the cleaners, and is of variable value, according to that of the first and second class ores.

4. Fourth class (*metal granza de labores*, or *tierras de labores*.) This comprises the smalls from the workings in the mine. Being generally mixed with considerable dirt it is inferior in value to any of the other classes.

On arriving at the hacienda, the large ore, *gabbaro*, is broken up to the average size of large peas, though some pieces may be as large as hazelnuts. This breaking is done either by hand (at a cost of \$2.66 a ton), or, in some haciendas, by rude stamps with wooden stems and iron shoes, the total weight of each stamp being about 300 pounds. These stamps are usually set in batteries of four or five, and are moved by a water wheel. At the hacienda of

the same time; an old one and a new one are always working together. From one half to two thirds of the charge is put into the *tahona* at starting, together with a few ounces of quicksilver to catch the fine gold, and just water enough fairly to wet the charge. As the grinding proceeds, the rest of the charge and more water are added, until, when the grinding is ended, the contents of the *tahona* are in the form of a liquid sand.

The *tahona* is made to revolve very slowly at first, but when the charge is well reduced in size, its velocity is increased, the rule being to run fast enough to keep the heavier parts of the charge from settling down and clogging the stones, and not so fast as to make the mud splash out centrifugally. The proper speed is usually from 9 to 10 turns a minute. When the bottom stones of the *tahona* are newly laid (*rehajado*), it is necessary before grinding good ore to grind up a few *cargas* (a Mexican *carga* is 300 pounds), of the lowest class of ore (*tierras de labores*), in order to fill up the cracks between the stones and prevent the escape of gold amalgam derived from the richer ores. The progress of the grinding is tested from time to time by taking an assay (*tentadura*) on a small

bottom, and there accumulates in the cracks and cavities of the stones. When the slimes (*lana*) are fine enough they are watered freely to facilitate the sinking of the rest of the gold amalgam; they are then dipped out into barrels, with the exception of about a barrelful, which is left behind to retain the amalgam, and are thrown into stone slime pits (*lameros*), where they are left to dry partially, by evaporation and percolation, before being put on the patio. When enough slimes have accumulated, they are carried to the patio in barrels, and a *trilla*, called in some parts of Mexico a *torta*, is formed. The *trilla* varies in size according to the richness of the ore and the size and resources of the hacienda, but it seldom contains less than about 10 tons, of 2,000 pounds each (60 Mexican *cargas*), or more than 25 tons. In very small haciendas, *trillas* of from one half to two tons are worked, but there the treading out is done by men and not by mules. Around the slimes, which are brought to the patio in a semi-liquid state, a dam of sand and boards is built up to confine them within limits; they are then left for several days, exposed to sun and wind, until the water evaporates and they acquire about the consistency of brickmaker's clay,

like all other systems of free amalgamation, is not successful with ores containing more than a trace of zinc or lead, the presence of zincblende being especially obnoxious. Iron and copper in small quantities are not particularly disadvantageous. The process succeeds very well with all sulphide ores which do not contain much more than a trace of arsenic and antimony, provided the tailings are concentrated, although, of course it is best adapted for free milling ores. For suitable silver ores that contain small amounts of free gold the process is still a good one, but where the gold is combined with sulphurets, a considerable and even an excessive loss is inevitable. Hitherto the Mexicans have submitted to this loss, but, since the introduction of American mills, they are gradually abandoning the patio process in favor of the other.

The San Dimas ores have a gangue of quartz and feldspar. They are composed principally of silver sulphides, with some chloride and some native silver, and they carry considerable gold. The impurities are copper pyrites, copper and iron pyrites, and, frequently, traces of zinc, antimony, and arsenic. The ores are cobbled and hand-picked at the mines, and come down to the *hacienda* sorted into four classes, in pieces whose sizes vary from that of an egg to that of an orange. The four classes into which

which I had charge, a Blake crusher has lately been introduced to do this work. The crusher is to be run by a belt from a spoon arrastra (*tahona*), and it is expected that the cost of crushing will be reduced to 30 cents a ton. The cost of crushing by stamps is at least 75 cents a ton. It is also expected that the product of the crusher will be much finer than can be readily obtained by hand or by Mexican stamps. This will leave less grinding to be done afterwards, and thus will increase the product of the hacienda.

The crushed ore is charged into the *tahona*.

An Arrastra Run by Water-Power.

Acting on a ring set with wooden spoons, which is, in fact, a horizontal water-wheel. The largest *tahonas* in San Dimas have the central cup (*tosa*), where the grinding goes on, 3m. in diameter and 0.5m. deep. The diameter of the spoon ring is 6m., and that of the circle touch-

ing the exterior extremity of the spoons is 6.64m. These *tahonas* are intended to hold 1,500 pounds of crushed ore, which they grind down to slimes in about three days. According to calculation the water used should develop, at ordinary times, about four horse-power, of which it is quite probable that not more than one quarter is utilized. The grinding-stones, when new weigh from 1,200 to 1,500 pounds; when worn down to about 400 pounds they are removed. Two new stones are never put in at

red earthen plate (*platillo*) from a point halfway to the bottom of the cup. When no grit can be perceived between the fingers, the grinding is regarded as complete. Horry-handed Mexicans, conscious of a want of sensibility in their fingers, try for grit by rubbing the assay on the lobe of the ear.

The Average Time of Grinding a Charge.

Which I alluded to above as three days, is generally shortened a little if the man in charge of the grinding (*tahonero*) is paid by the number of *cargas* ground, and not by the week. A good *tahonero* gets ten dollars a week, or, if paid by the *carga*, from 15 to 20 cents a *carga*. He has to be on hand night and day, sleeping close by his *tahonas*, and making his rounds several times in the night to see if all is well. It is hardly necessary to say that strict honesty is a most essential requisite in a *tahonero*, for his opportunities for stealing quicksilver, gold amalgam, and ore, are unlimited. In *tahonas* moved by spoons, the grinding, including salary

and repairs, costs \$1.40 a ton. In some haciendas the *tahonas* are placed in groups, and are driven by an overshot water-wheel, the power being transmitted by rude wooden gearing. Although these *tahonas* are smaller, they grind more rapidly, and the cost of attendance is less, so that the cost of grinding is probably not more than \$1 a ton. During the operation of grinding, the

Free Gold in the Ores

Is caught by the quicksilver, and the greater part of the gold amalgam formed sinks to the

which is the proper state for the beginning of work.

Leaving the slimes on the patio for the present, let us return to those remaining in the *tahona* and

Containing the Gold Amalgam.

After a variable number of charges have been ground, and from four to eight pounds of quicksilver have been taken up, a few ounces at a time in each *tahona*, the process of grinding is stopped, and the whole interior of the *tahona* is scraped out with the most scrupulous care. The whole amount of material thus collected is washed in a pit, known as a *chuza*, and the gold amalgam is carefully collected. The *chuza* is about 3 m. in diameter, and 0.5 m. deep. It contains at one side a conical wooden bowl, 0.35 m. in diameter and 0.3 m. deep, whose edges rise about 0.05 m. above the cemented bottom of the large pit. A wooden trough conducts water to the pit, and opens into it directly over the bowl. The material to be washed is put into the trough, in which it is carried gradually along until it falls into the bowl. A man or boy sits over the bowl and keeps the material in agitation by stirring it continually with his foot. In this way the slimes to be washed are thoroughly disintegrated, the quicksilver and the amalgam fall to the bottom of the bowl, the heavier tailings collect in the pit, and the lighter ones are carried away by the water to a settling-tank, or run to waste. The tailings saved in the pit are concentrated by hand, and usually yield some very rich sulphurets, containing large quantities of both silver and gold (*cabezele*). The gold amalgam is wrapped in a cloth, placed inside of a quicksilver flask with the bottom out, or in a small earthen pot, if too small for the flask, and retorted in the usual Mexican manner, of which a description is attempted further on. The resulting spongy mass of bullion is called *oroche*. The quicksilver used in collecting gold in the *tahona* is kept

apart from that used for silver on the patio, as is very rich in the precious metals, and will catch the free gold more quickly than fresh quicksilver.

The Slimes left on the Patio

To allow the surplus of water to evaporate should be found to have, after an exposure of two or three days, according to the weather and the season of the year, about the consi-

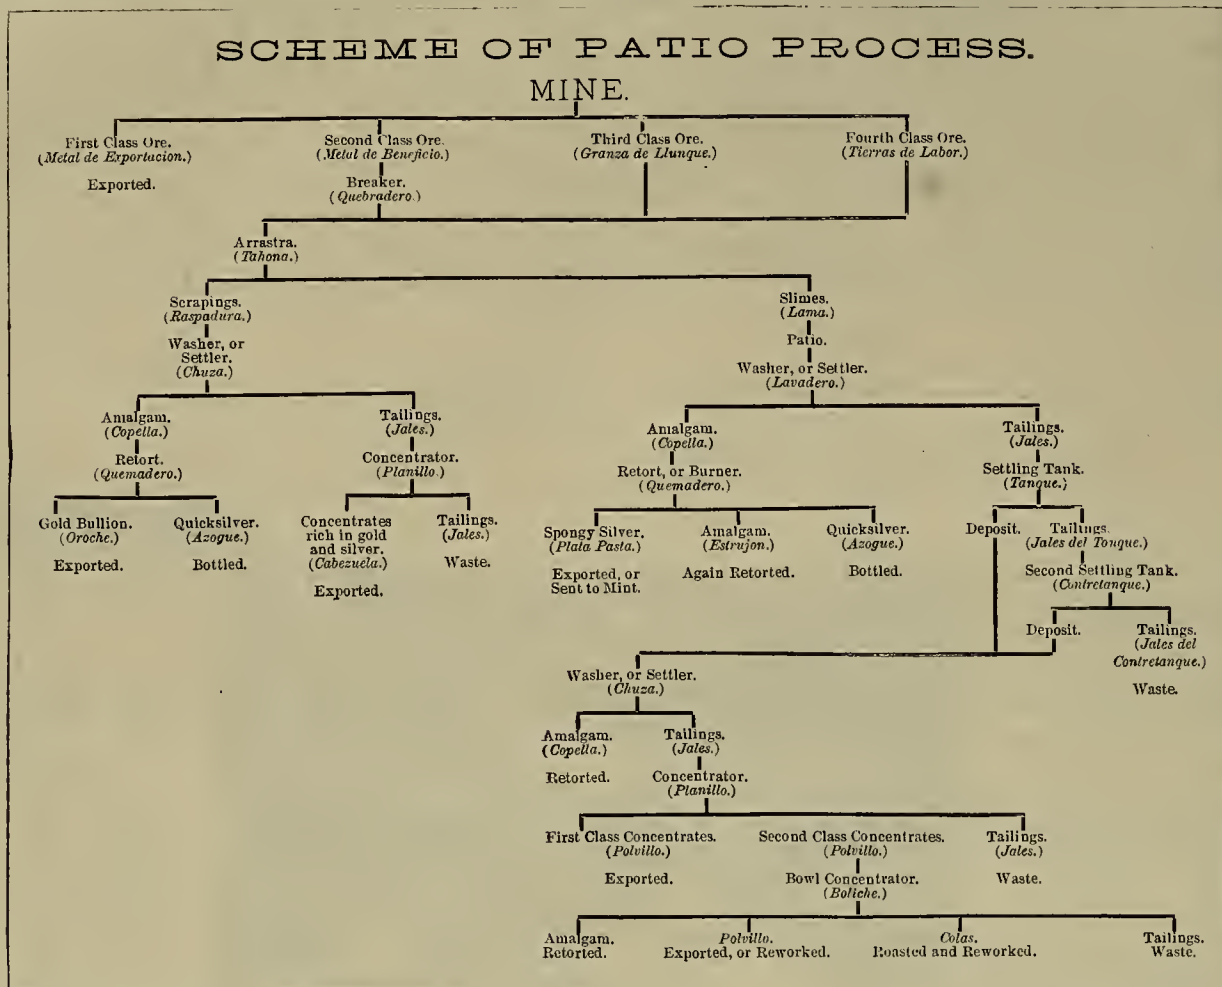

amount to be added varies according to the nature of the ore. Ores with no sulphurets need very little sulphate; those with sulphurets and with traces of antimony, arsenic, or zinc, need the most, and only the experience of the amalgamator can tell him how much to add in each case. For sulphureted ores with only a trace of antimony and arsenic, and no zinc, it is customary to use about eight pounds for each ton of ore. In place of a part of the sulphate of copper

copper is thought to hasten the beneficiating and to lessen the loss of quicksilver. Magistral is not used in San Dimas.

After the Sulphate is Added,

The mules are driven around in the trilla until three o'clock in the afternoon, at which time the silver-bearing mud is carefully washed off their sides and hoofs, and they are led away to pasture. The day's work for the mules is from 6 A. M. to 3 P. M., and it is very fatiguing and

The next day after incorporate, another treading (*repaso*) of the trilla follows. Then there is a day's rest and exposure to the sun, whose effects are stimulated by one or more spadings. If the mass gets too stiff from evaporation, water is dashed over it to keep it sufficiently moist for easy working. The application of water should always be made in the early morning, so as not to cool off the trilla and retard chemical action, as it would do if added at mid-

tency of brickclay. The first thing done with them is to turn them over with a spade, and trim up the mass until it assumes the appearance of a gigantic "dirt-pie," 7 to 15 m. in diameter and from 0.2 to 0.3 m. in thickness.

Twenty-four hours after the first spading, the trilla is salted (*insalmoro*). The quantity of salt used varies according to the character of the ore; but, for sulphureted ores that average \$60 a ton, the quantity used should be from 35 to 40 liters a ton. Mules are then turned in and made to tread the mass for some hours, until, with the help of several spadings, done while the mules are resting, the salt is thoroughly distributed through every part. The number of mules need not be so great as when the full charge of quicksilver and chemicals is in. The trilla stands in this condition over night; the mules then tread it for an hour or two to loosen it up; it is spaded over again, and the charge of quicksilver and sulphate of copper is added. This stage of process is called *incorporo*. The amount of quicksilver added at the incorporate varies according to the nature of the ores and the special practice of the amalgamator (*azoguero*). The total amount required can be closely calculated from a fire-assay of the trilla. The yield of silver on the patio is usually calculated at 65 per cent. of the total amount contained in the ore, and the rule is to allow six pounds of quicksilver for each pound of silver, an additional 150 to 200 pounds just before washing to keep the silver amalgam in a fluid state and to promote its separation from the tailings, and seven per cent. more for mechanical loss during the process.

Those who believe in putting in a small charge at first say that by doing so they avoid mechanical loss, since the bulk of the quicksilver is not so long on the patio; others argue that this gain is visionary and does not equal the cost of putting in the quicksilver afterwards. Whatever the amount of quicksilver may be, it is emptied, ten or twelve pounds at a time, into a doubled piece of cotton cloth, and a sturdy laborer then walks all over the trilla, squeezing the cloth with both hands and flinging the quicksilver in a shower over the trilla, as it is forced in small globules through the pores of the cloth. Care must be taken not to fling any quicksilver away from the trilla on to the patio, and to distribute it uniformly; the rest of the operation is merely mechanical.

After the quicksilver has been added the treading begins again with full completeness of mules, one for each ton and a half of ore in the trilla, and continues, with one spading over, for two hours. Then the mules are again stopped and a hot solution of sulphate of copper is added. The

some amalgamators use metallic copper in a finely divided state (*precipitado*), obtained by precipitation from sulphate of copper solution on iron or zinc. That obtained by aid of zinc is supposed to be distinctly better than that obtained by iron. When used together, five parts of sulphate and one part of the precipitated copper are added to the trilla. The use of metallic

exhausting to animals not brought up to it. They are driven around in teams of not more than nine, a driver standing in the middle of each team with the ends of the halters and a big whip. The mules are made to walk in spirals so as gradually to get over every part of the mass. In large trillas two teams are often at work at the same time.

day or in the evening, when the trilla has been well warmed up by the sun's heat. The sun, indeed, is to the patio process what hot pans are to a regular silver mill. The influence of a warm, bright day upon a trilla is very great, while a cloudy or cold day retards its progress surprisingly. The progress of the amalgamation is carefully noted by means of assays (*tentaduras*), which are washed two or three times a day in the red earthen plate (*platillo*) before mentioned. This plate is about 0.18 m. in diameter, 0.007 m. thick, and about 0.02 m. deep at its deepest part.

An assay skillfully washed in such a plate presents several

Deposits of Different Substances.

The plate is held in a slanting position at the end of the washing, and the different substances arrange themselves from above downward. First there comes a silvery white crescent of amalgam (*ceja*), then a black crescent of rich sulphurets, followed by a brownish deposit of pyrites with glittering specks, which runs off into sand at the lower edge. Below all a half spoonful of water contains a little hall of quicksilver. Most of the conclusions as to the state of the trilla are formed from the appearance of the upper rim of amalgam. When this is crystalline and hard to be worked by the fingers into a coherent mass, and no globules of quicksilver can be squeezed out of it, the amalgam is said to be "dry," or "strong" (*fuerte*), and the condition indicates the need of more quicksilver. When quicksilver is present in excess, a coherent mass is readily formed under the finger, and little globules of quicksilver are easily forced out. At the conclusion of the amalgamation the trilla is said to be *rendida*, and when this is the case, the rim of amalgam is very fluid, and at a touch resolves itself into small globules, and vanishes away. When in this state, or approaching it, it is said to be weak (*debil*). A white, clear, bright appearance of the amalgam ring indicates that it is going well, while a dark, dirty color shows that something is wrong, and calls for a modification of the course of treatment. The ball of quicksilver in the lower part of the plate is also an indicator of the state of the trilla. When bright and clear, it shows that all is well, but if it is dark in color, and especially if surrounded by a dirty, furry jacket, something is very much out of order. Sometimes the signs are all right, but the amalgamation does not advance. Assays washed on successive days show the trilla to be at a standstill. This arises from a want of salt or from cold weather. Other abnormal appearances arise from too little sulphate, too

little salt, too little or too much treading. Irregularities of this kind can only be effectively dealt with after considerable experience. As a general thing, however, a trilla, when it goes wrong, is treated either for "heat," arising from an overdose of sulphate and overworking, i. e., from too energetic chemical action, or for "cold," arising from too little salt, too little sulphate, or too little treading. A heated trilla can often be restored, especially during the cold weather, by simply letting it stand a day or two, by dashing cold water over it, or by an application of lime and ashes. The heating, however, generally involves a loss of quicksilver, as the sulphurets under such circumstances seem to attack it strongly. For a "cold" trilla the treatment is to supply what is wanting. This is ascertained by taking several larger assays, of from two to five pounds each, called *jualas*. To one of the assays a little salt is added, and to another, sulphate of copper. These are worked in a little by hand, and the masses are allowed to stand in a warm place. To a third assay no chemicals are added, but the mass is vigorously kneaded by hand for some time and is then left to itself. A tentadura of the assays, made after some hours, will generally show what the matter is with the trilla.

During the working of the Trilla

Quicksilver is added from time to time, as determined by the indications of the assay, and, if everything goes well, the amalgamation ought to be finished after six or eight treadings. This desirable result depends, as has been already remarked, on the weather; gloomy, cold, and rainy days set a trilla back wonderfully, and a heavy rain will often make the mud so liquid that no work can be done on it for several days. Under favorable conditions the operation from incorporate to washing (*lana*) can be completed in 16 days; while, under unfavorable circumstances, I have known a trilla to be on the patio between five and six weeks. About three weeks is the average time of working. The best way is to pay the amalgamator by the carga of ore worked (25 cents a carga or \$1.66 a ton is the usual price), as by this system the work goes along much more rapidly than when the same man is paid a fixed salary. There is, however, a temptation to wash the trilla before the amalgamation is complete. To avoid this the proprietor should have some knowledge of the process, should give a general supervision to the operator, and pay constant attention to the assays.

As soon as the amalgamation is completed preparation must be made for washing the trilla within 24 hours. If the trilla is allowed to stand for a longer time a further action takes place, called *desecho*, in which the surplus chemicals or the sulphur attack the amalgam and cause a great loss of silver. In order to guard against this danger, and to liquefy the amalgam, the 150 to 200 pounds of quicksilver before mentioned are added as bano, and preparations are made for washing and settling.

The Ordinary Settler

(*lavadero*) is an open box of stone-work, lined with cement, 2 m. long, 0.5 m. wide, and 1 m. deep, with a platform at its mouth on which to pile up the material to be washed, a trough to fill it with water, and, at one end, a wooden gate pierced with a series of two-inch holes. These holes are kept closed by wooden plugs, and have a vertical trough outside to conduct the discharge to a quicksilver trap below.

At some haciendas of large capacity there are settlers, driven by water-power, that consist of large wooden tubs, some 2 to 5 m. in diameter by about 3 m. in depth, in which revolve vertical shafts carrying four arms. These arms are pierced with square holes, in which are inserted vertically sticks of wood about 0.06 m. square, with intervals of 0.1 m. between them, the whole combination resembling a pale fence with the edges of the pales set diagonally to the side of the fence. These dashers reach to within about 0.3 m. of the bottom of the tub. A water-wheel by means of wooden gearing turns the upright shaft, and thus the contents of the tub are kept in violent agitation. About 0.8 m. from the bottom of the tub there is a hole about 0.15 m. in diameter through which to empty the tub, when desired; and about 0.15 m. above this there is a smaller hole, about 0.02 m. in diameter, for the taking out of assays.

In the ordinary box-settler the procedure is very simple. Inside the box, instead of wooden arms driven by a water wheel, there are two men, whose business is to keep the contents in motion. The box is partially filled with water, and the men get into it with only a breech-clout to cover their nakedness, and the mud from the trilla is tumbled in, a spadeful at a time. By a dancing motion of the feet, the hands never being used, the mud is disintegrated and kept in suspension, so that the amalgam sinks to the bottom. More water and more mud are added, little by little, until the settler is filled to the highest hole in the wooden gate. The lighter tailings flow out through this hole with the water, and are conducted by a series of gutters, well provided with catch basins for quicksilver, to the settling tanks below. The muddy contents of the *lavadero* are partially discharged from time to time during the day through one of the lower holes in the wooden gate, but the amalgam goes on accumulating until the end of the operation. Care is necessary not to wash too fast, for fear of letting too much quicksilver run out of the settler, but the mass must be kept in constant agitation and not allowed to get too thick, for, if it gets too thick, the lower part of

the settler becomes clogged with tailings from which the quicksilver can be separated only with difficulty.

In the tub-settler the machinery at first is made to revolve very fast, with the tub a third full of water, and the charge is then tumbled in and disintegrated at once. The tub is then filled nearly to the brim with water, and the dasher is reduced in speed and kept moving only just fast enough to keep the sand from settling, until several assays, taken from the small hole in the side, show that the quicksilver has settled. When this stage of the process is reached, the plug closing the large aperture is knocked out, and the tailings escape into the troughs leading to the settling tanks. The time of washing a charge of 300 pounds is about one hour. There are great advantages gained in using the water-power settlers. The operation can be kept up day and night until finished, whereas, with the box settlers, a clean-up must be made at nightfall. There is less chance for the workmen to steal, since only two men are needed besides the overseer, while the box settler requires at least six men. There is less danger of the sand settling and clogging the amalgam, or of the quicksilver being carried off with the tailings; and, as a whole, the operation is under better control in every way. The first cost of the plant, however, is considerable, and, as surplus capital is not abundant in Mexico, the tub-settler is not used, except in haciendas of the first class, and I am not sure that it is not of comparatively modern introduction even in these.

Whichever method of settling is adopted, the last part of the operation consists in scraping the stones of the patio where the trilla lay, and the cracks between them, and throwing the scrapings into the settler with the last of the trilla.

The Construction of the Patio

Is simple. The common patio of the country is composed of irregular stones with surprisingly wide cracks between them. The flattest stones at hand are selected and laid in, without "facing," to be smoothed down by natural wear. The cracks are filled with clay. The loss of quicksilver is not so great as one might suppose; with skillful working on an old patio the loss should not be over seven per cent., a part of which would be due to evaporation, and a part would be splashed away by the mules or lost in the crevices of the *lavadero*. The earth underlying the patio becomes in course of years well soaked with quicksilver; so that it sometimes pays to clean it up, especially if the hacienda is to be abandoned. Efforts have been made to improve on this older style, and in one hacienda in San Dimas the patio is made of brownstone, faced and fitted with great exactness. The cost was enormous, and it is doubtful whether a year's saving in quicksilver would pay more than a moderate rate of interest on the investment. In some places patios have been paved with pine planks, tongued and grooved. In them the mechanical losses are small. They last for several years, being always kept flooded with water when not in use, and being protected besides by the strong preservative action of the sulphate of copper. I have also heard of patios built of asphalt and of artificial stone, both of which seem to be exceedingly well adapted to the purpose. Various mechanical expedients have been tried in San Dimas for the purpose of treading the trilla without mules. Rollers, wheels, and other devices have been used, but have all been abandoned. The day has gone by for investing money in an expensive plant for a process so radically defective, and the modern tendency is so manifestly opposed to such expenditure, that the most conservative Mexicans have already perceived it.

The yield of the washed trilla is chiefly found in a pool of liquid amalgam at the bottom of the settler. This amalgam is carefully dipped out, cleaned, dried, and weighed. The catch-basins in the gutter, through which the tailings had to pass on their way to the settling tanks, are also cleaned up, and the quicksilver they contained is weighed with the rest. The whole is then turned into a conical canvas bag (*manaya*) to drain. The drippings are received in a hide trough (*pila*), and decanted into flasks, being practically, though far from chemically, free from silver. The dry amalgam (*capella*) left in the bag is allowed to hang over night, and is then packed for retorting.

The Retorts of the Country

Are iron quicksilver flasks, with the bottoms knocked out, and the plugs firmly screwed in. These are first lined with brown paper, and then the amalgam is put in and rammed down firmly with aid of a wooden rammer and a heavy mallet. When all the amalgam is ready, the flasks are placed upon the furnace (*quemadero*). This furnace has a flat top, about 0.6 m. from the ground, pierced with four, six or eight holes, 0.12 to 0.13 m. in diameter, which is slightly more than the outside diameter of a quicksilver flask. From these holes pipes of the same diameter lead well beneath the surface water contained in a wooden basin below. The upper ends of the pipes are covered with iron plates pierced with many holes about 0.005 m. in diameter. Upon these plates the flasks filled with amalgam are placed, the open end downwards. A clay lute is then applied around the mouth of each flask, and the whole flask is covered with a neat coating of clay, about 0.005 m. thick. When all the flasks are in place and luted, a temporary wall of bricks is built around them, as they stand on the table of the *quemadero*, and a charcoal fire is kindled. The flasks are heated slowly until the lute and the clay coatings have dried with-

out a crack; then more and more charcoal is added until the whole mass of flasks is covered with glowing coals. The volatilized quicksilver finds its way down the iron pipes into the water, and condenses in a shining pool at the bottom of the basin. The water in the basin is constantly changing, and the condensation goes on until the operation is completed. Simple as the retorting is, it needs care. Too much heat will melt the silver, and cause it to follow the quicksilver down into the water, or it may cause a too rapid formation of quicksilver vapor and an explosion, in which a flask of amalgam, hurled high in the air, distributes its valuable contents far and wide. If the heat is too low, too much quicksilver is left behind with the silver. When the operation is properly conducted, the silver comes out in spongy bars (*plata pusa*), containing still about one per cent. of quicksilver, which can only be removed by melting the mass to an ingot. As a precaution against the possible presence of an excess of quicksilver, the purchaser of this kind of silver always has the privilege of heating the bars to a red heat before weighing them for final acceptance. If, however, they melt while undergoing the trial, the purchaser must pay for them at their weight before being put into the fire.

The quicksilver collected in the basin of the *quemadero* is not entirely free from silver. Before being put back into flasks, it must be strained through a closely woven cloth. This saves a certain amount of amalgam, called *estrujon*, which is much more pasty than that put in to be retorted. When a sufficient quantity of this kind of amalgam has accumulated, it is retorted over again. In the retorting there is a mechanical loss, from leakage, of a few pounds of quicksilver.

The Silver obtained by the patio process is almost entirely free from the baser metals and from impurities of any kind. An assay of several bars gave an average of 994-1000ths of silver and 34-1000ths of gold, leaving only 25-1000ths for the baser metals, dirt, and loss. From 70 to 75 per cent. of the assay value of the ore in silver can be extracted by careful working, though the ordinary amalgamators do not get over 72 per cent. Some amalgamators claim that they can save 80 per cent. of the assay value, but this is extremely doubtful. Of the gold in the ore at least 40 per cent. is lost, about 20 per cent. of the remainder goes with the silver, and the rest is recovered from tailings, or is caught in the tahona.

The loss of Quicksilver

In the patio process is very great. There is always a fixed loss of an amount equal in weight to that of the silver taken out; this is called *consumido*. Besides this, there is a mechanical loss on the patio and in washing of at least seven per cent., which the least carelessness may increase to 10, and there is a further loss of from four to eight pounds in the retorting, so that, in the working of sulphurets, that yield on the patio from \$60 to \$90 a ton, the total loss of quicksilver is, even under the best management, seven and a half pounds a ton; for ores of higher value, the loss is more.

The tailings from the washer run into two settling tanks, called *tangue* and *contratangue*, passing from the first into the second. A settling tank for trillas of 12 tons each is 5m. long, 3 m. wide, and 1 m. deep. In these tanks the tailings leave the heavier sulphurets and a small quantity of amalgam with the heavier parts of the sand. The lighter portions of the tailings flow through the *contratangue* to waste. There is a great difference in the contents of the two tanks. The *tangue* contains more and richer sulphurets, while the deposits in the *contratangue* are notably poorer in quality and less in quantity. In the subsequent concentrations it is customary to keep the material from the two tanks separate until a fire assay determines their fitness to be mixed.

The Concentration of the Tailings

Is preceded by washing them a second time in the chuzas, already described, for the purpose of getting out any remaining amalgam: The yield is usually three pounds or upwards, according to the size of the trilla and the carefulness of the former washing. For concentration the tailings from the chuzas are piled up at one end of a masonry platform (*planilla*), from 1.5 to 2 m. square, with a slope of 1 in 10 towards the workman. The head of the platform is a sloping wall, which leaves space to accommodate a reserve of tailings, and at the foot there is a wide gutter with plenty of slowly running water. The operator (*planillero*) sits on a board thrown across the gutter at the lower left-hand corner of the planilla, and, lifting up the water with a horn spoon, about a quarter of a liter at a time, discharges it against the foot of a heap of tailings piled up at the head of the planilla. He commences at the lower left-hand corner, continues across the planilla, and then returns a little lower down, throwing each spoonful of water in such a way that it spreads out without splashing, and overlaps a little the area covered by the preceding one. When he has gone over the whole surface of the planilla in this way some four or five times, the sand has been partially washed away from the heavy sulphurets, which have settled near the upper part of the planilla, while the sand has worked along down to its lower end. The operator then removes the sand from the planilla for about one meter upward from the gutter and throws it away. The remainder of the layer on the floor of the planilla he mixes up with the tailings at the head, and begins to throw on water as before. When the supply of tail-

ings at the head is exhausted, more are added and the process continues until all the tailings have been washed, and there is left on the planilla a black heap of sulphurets (*polvillo*.) In order

To Concentrate the Sulphurets

A little more and to extract the last traces of amalgam it is customary to put them through still another process, called *bolicheo*. This is performed in a wooden bowl, called *boliche*, whose cavity is shaped like an inverted cone, somewhat truncated, 0.62 m. in diameter, and 0.4 m. deep. Some boliches are 0.8 m. in diameter and proportionately deep; but, as they are made of a single piece of wood, such large ones are rare in San Dimas, which is "a long way from tall timber." Portions of the sulphurets are placed in such a bowl with plenty of water, and are vigorously stirred for some minutes, after which they are allowed to settle. During the settling, the outside of the bowl is tapped briskly with a heavy stick or mallet. This tapping is continued until the sulphurets settle down firmly and solidly in the bottom of the bowl, with all the water on top. The water is then absorbed by woollen rags and removed. On the top of the sulphurets there is a layer of pure sand. Below the sand there come first a layer of poor, brownish sulphurets called *colas*, and then the rich black sulphurets (*polvillo*). In the bottom of the bowl there is a small amount of liquid amalgam.

The *colas*, when a heap of them has accumulated, are roasted preparatory to working on the patio. The roasting furnace is made by spreading on the ground a layer of wood and kindlings, over which is spread a layer of *colas* about an inch thick; over the layer of *colas* there is another layer of wood, followed by another of *colas*, and so on alternately, always leaving a central opening, until a conical mound has been formed. The *colas* are put on wet, so as to be more easily handled. The mound, when completed, is covered with earth, set on fire, and allowed to burn out. In this method of roasting, one portion is over-roasted and sintered; a little is roasted just right, and the rest is under-roasted. The whole mass is mixed with sand, ashes and half-burned sticks. The sticks are taken out by hand and the mass of *colas* is thrown into a tahona to be re-ground. It is afterwards mixed with ordinary ore and worked on the patio.

The concentrated sulphurets are sent to the port of Mazatlan, and thence shipped to Germany for account of mine, to be worked in the government establishments there. Notwithstanding high freights, etc., the returns are from 15% to 20% better than would be obtained by sending the same sulphurets to San Francisco. The forwarding houses in Mazatlan usually make an advance of 70% or 75% on the assay value of the sulphurets, for which no interest is charged unless the returns are delayed beyond a certain number of months. The first-class ores mentioned above are sent in the same way.

The Cost of Working Ore

Upon the patio is very great. The following figures are from a hacienda where ores were worked whose average yield was \$60 a ton:

Process.	Cost per ton of 2000 lbs.
Breaking, grinding, and use of tools.....	\$1 52
Amalgamator's wages.....	1 40
Scraping tahonas.....	13
Carriage of slimes from tahona to patio.....	60
Mules.....	1 73
Labor.....	1 80
Salt.....	2 80
Sulphate of copper.....	1 33
Charcoal, for retorting and assaying.....	33
Quicksilver.....	4 68
Salaries, general expenses, etc.....	6 66
Repairs.....	2 33
Concentration of sulphurets.....	2 26
Total.....	\$27 58

The cost does not include cost of superintendence nor interest on cost of plant. The trillas upon which this calculation was based were small, averaging only ten tons. The expense of trillas of from 15 to 25 tons would be proportionately less in the items of scraping tahonas, mules, labor, repairs, and general expenses, and there would also be a smaller mechanical loss of quicksilver.

In a large hacienda, where the tahonas are in two groups and were worked by gearing from an over-shaft water-wheel; where the breaking was done by wooden stamps shod with iron, and also driven by a water-wheel; and where the washing was done in a water-power washer, the charges in detail for working a trilla of 19 tons, were as follows:

Process.	Cost per ton of 2000 lbs.
Breaking, grinding, and use of tools.....	\$6 86
Amalgamator's wages.....	1 66
Scraping tahonas.....	16
Carrying and washing scrapings.....	11
Concentrating tailings of scrapings.....	97
Carrying slimes from tahona to patio.....	42
Mules and keeping.....	3 72
Labor, spading trilla, and mule driving.....	1 69
Labor, washing trilla.....	56
Charcoal for retorting silver.....	47
Concentrating tailings of trilla.....	2 06
Materials:	
Salt.....	2 53
Sulphate of copper.....	1 65
Precipitated copper.....	87
Quicksilver.....	4 37
Total.....	\$26 91

The total cost of \$26.91 a ton for custom work in this hacienda includes a charge for profit to the owners on all the items except the four items of "materials," which were originally higher priced; they have been reduced to the same prices as in the other table to facilitate comparison. To the owners of the hacienda the cost of beneficiating would certainly not exceed (CONTINUED ON PAGE 192.)

Geography and Climate.

Magnetic Declination.

every degree of latitude we travel to the north.

General Geological Characteristics.

I have noticed on the coast of Vancouver's island and the main land that the striations made by ice action on the rocks are very distinct, and indicate an ice motion toward the south-

all located round one elevated quaquaversal point in the Rocky mountains, namely: Mount Brown, which attains an altitude of 19,000 ft. From this point the Fraser and Columbia rivers trend away towards the south. The Assiniboine toward the east and the Athabasca and Peace rivers run northerly and discharge their waters into the great Mackenzie river, which empties itself into the great polar basin. This river,

The evidence of the glacial age are everywhere apparent. Professor Richardson considers that one large glacier, 50 ft. miles in length and 600 in thickness filled the Straits of Georgia. Observations made by him in the northern part of the straits show where the source of the great glacier must have been ice action to a height of over 3,000 ft. being exhibited. In the interior plateau of this region there is a system

The principal rivers of British Columbia are

the Hudson Bay Co. officials say has a course of 2,500 miles from its source and is navigable for steam boats for 1,200 miles. But its mouth must forever remain ice-barred against navigation. No salmon have ever been caught in any of the head waters of this river; but in the Fraser and Columbia rivers before alluded to, also in Stickcen Nass, Skeena and other rivers which head in the Coast range the finest salmon are found. The coast and inlets of British Columbia are also well stocked with many kinds of salt water fish. A good many

salmon canneries are in operation during the fishing season on the Fraser, Nass and other rivers, and a large number of cases are shipped abroad.

The staple commercial timber of British Columbia is *Pinus Douglasii*. This is largely manufactured and shipped abroad. I have seen sticks of this timber 180 feet in length almost clear of knots. It grows to the 52 parallel of

east of the Mississippi river cease to be productive, and the shales and sandstones associated with the coals of the East are gradually replaced by limestones which underlie the great plains. The coal mines of British Columbia, and no doubt the whole of the Pacific coast, belong, first, to the lower cretaceous, holding the anthracites of Queen Charlotte Islands; secondly, cretaceous rocks holding the Nanaimo coals; thirdly,

PLACE.	Thickness of seam in feet.	Water.	Combustible matter.	Fixed Carbon.	Ash.	Sulphur.

Wellington (Dunsmuir).

North Thompson river, bituminous coal of good quality; Lillooette, bituminous coal; South fork Similkameen river, lignites; Lightning creek (Cariboo), lignite; Fort George, lignite; Peace river and Pine river, beds of bituminous coal; Parsnip, Nechacho and Chico rivers, lignite. The Skeena river is also said to flow through an extensive formation of coal beds, from 3 to 35 ft. thick. On Vancouver's island coal has been found at Quatsino sound, Beaver harbor, Fort Rupert, Alberici canal and Cowichan bay. By a process of inductive reasoning, assuming as premises the localities and figures given in above schedule, we arrive at these conclusions: That the coals of the north contain the greatest amount of fixed carbon, and those toward the south gradually become more bituminous and less carboniferous until the coals of the Fraser river basin and Puget sound are reached. These assume some of the characteristics of lignite, and of course are of inferior quality to any of the preceding varieties.

According to the private circular of J. W. Harrison, the receipts of coal for the past year, at the harbor of San Francisco, were 846,000 tons. The portion of this amount received from British Columbia was only 151,800 tons. When we consider that the coal fields immediately trending along the coast of British Columbia have been estimated to cover an area of 3,000 square miles, the amount of coal raised and shipped to the San Francisco market looks very small, although the price paid by retail was very liberal, namely, about \$12 per ton. (Coals in Colorado are put on the cars for \$2 per ton). As a change of government has lately taken place in British Columbia, it is to be hoped that a more enlightened and statesmanlike policy will prevail than in the past, and that coal lands which have been reserved from sale during past years will be sold to enterprising capitalists (not monopolists) on this coast to open up. This policy would lessen the price of coals in San Francisco and greatly enhance the wealth and prosperity of British Columbia generally.

Some 300 square miles of anthracite coal fields are said, by Professor Richardson, to be located on Queen Charlotte island. This coal gives 85 per cent. fixed carbon, and equals the best Pennsylvania coal.

The total thickness of rocks associated with the coals of British Columbia are the following, in descending order: Upper conglomerate, 320 feet; upper shales, 776 feet; middle conglomerate, 1,100 feet; middle shales, 76 feet; lower conglomerate, 900 feet; lower shales, 1,000 feet; productive coal measures, 739 feet; or in round numbers, about 5,000 feet. The thickness of rock associated with coals in the eastern states of America is 15,000 feet, and in England about 11,000 feet. The tertiary coal measures of the Sound and Bellingham bay are continuous north of the 49th parallel, and must underlie nearly 1,000 square miles of the low country about the estuary of the Fraser river.

Localities of Other Minerals.
It will be proper to consider some of the other places where the economic minerals of commerce are found in this region. Iron is found widely distributed over the country. Some of the principal localities are Texada island (magnetic); Queen Charlotte island (clay, iron, stone associated with coal); Iron mountain, Nicola, specular iron; Cherry Bluff, Kamloops lake, (magnetic); and Baynes sound (clay, iron, stone associated with coal). Assays: 36.83 metallic iron.

Copper is found at the following places: How Sound (copper or eubecite masses have assayed \$75 per ton silver), Sansone Narrows, Dean Canal, Harrison river (purple copper), Fort George, Copper Island, Copper Creek and Homathco river. Antimony (Stibnite) is found at Little Shuswap Lake, and at Kumsishaw, Queen Charlotte sound.

A very large deposit of quicksilver has been found on the Homathco river; also float ore on Watson Creek, Fraser river.

Platinum is found in scales on Similkameen river.

Silver is found at the Eureka mine, Fort Hope (rich ore, bromide), Cherry Creek (rich ore, assays from \$300 to \$5,000 per ton not yet prospected, Freibergite). Vital Creek (Omineca argenterite) assays 83 per cent. silver (specimen at State Mining Bureau, San Francisco) Similkameen river. Quantities of silver have been found in gold placers on Francis river and Quartz Creek Cassiar (a vein which has assayed \$200 per ton exists there), Cowichan, Vancouver's island (argenteriferous galena); and on the

north latitude on the coast. Further north white cedar and spruce are large and abundant.

Minerals of British Columbia.

Regarding the minerals of British Columbia, I shall in the first place note its coal formations and coal. A line drawn on the 97th meridian of west longitude from Greenwich pretty exactly separates the coal-bearing formations of America into two classes. West of eastern Nebraska, the carboniferous formations which yield the coals of Nova Scotia, and the States

the tertiary formation with its bituminous coals and lignites of the Fraser river and Puget sound basins. The rocks associated with the cretaceous and tertiary coals are superimposed upon the crystalline rocks. The mountain limestone which forms the base of the carboniferous coals to the east of 97th meridian, above stated, is waiting on the Pacific Coast. The following schedule will show the localities where coals have been found in British Columbia, and an analysis of some varieties of them;

seam).....	4 " 6	34.70	55.50	9.80

* Fine coke.
† 50 miles from mouth of Fraser river.
Other localities where coals have been found, but have not been analyzed, are as follows:

Kootenay country to the east of the Columbia river, ledges of gold and silver quartz have been found.

Gold is found in placer diggings at Cariboo, Omineca, Cassiar and Kootenay. Average number of miners employed 3,220; average earnings \$658 per year; total and actual estimated yield of gold from 1858 to 1876, \$38,166,970—and calculating on this basis up to the present time and deducting 25 per cent. for exhausting of placers, the amount would be \$47,708,713 up to 1882. This gold was all taken from placers. No quartz mining is carried on in British Columbia, although some excellent ledges have been found. (Facts taken from Government reports).

Railroads.

It is the intention of the Dominion government, that their contractor, Ouderdonk, will have the railroad completed from Port Moody on the sea board, to Savanas Ferry by next year. The line located by the Dominion government surveyors trending north, is to be abandoned, and Colonel Rogers explored line for the syndicate, adopted in its place. This change will shorten the distance east some 150 miles, but will increase the altitude of summit level of railroad over the Rocky mountains some 1,000 ft., namely, from 3,700 ft. to nearly 5,000 ft; but as Rogers' line runs across the mountains about two degrees of latitude, or about 138½ miles further south than the first located line, the difficulties to be overcome, caused by winter snows, may not be greater, and the cold not more intense.

The Mining Laws.

Any man is allowed by law to take up 1,500 feet along a lode of quartz, and 300 feet on each side of the center line, measured on a line at right angles with said center line.

The dips, spurs and angles of the lode can be followed although said dips, spurs and angles may diverge outside of the vertical planes bounding the said claim produced downward from the superficial boundaries.

The qualification of citizenship is not necessary as in the United States, but only applies to cases of land pre-emptions for agricultural purposes.

Any man, whether an alien or otherwise, can purchase coal land on the west side of the Cascade range of mountains for \$10 per acre, and on the east side for five dollars per acre.

Agricultural land can likewise be bought in any part of B. C. for one dollar per acre.

Alaska.

The number of men at present employed in mining pursuits in this region is about 600. Extensive quartz lodes have been found in Douglass island, near Harrisburg; the assay value of rock is not high, but the extent of the lodes and their proximity to the salt water make them valuable. Two quartz mills of five stamps each are at work on the quartz lodes. The geological formation along the Alaska coast is (Crystalline), clay, slates and granite. An examination of the coast extending to 150 miles north of Fort Simpson was made by Professor Richardson, Dominion Geologist. The fisheries are extensive and doubtless the same enterprise which has developed the resources of the Pacific Slope will make it a prosperous territory. Authorities consulted; Professors Richardson, Selwyn and Dawson, Dominion Geologists, Professor Dove's and Professor Bache's charts, and my own observations, extending over a space of time amounting to 22 years, during which time my business as land surveyor and engineer necessitated my traveling over the region of country before described. To Capt. Oakford I am indebted for the foregoing information about Alaska.

W. D. PATTERSON.

THE SANTA RITAS.—The Tombstone *Republican* says: More than a passing interest is now being taken in the Santa Rita mountains; several important sales of mining property having lately been made, and good ore bodies developed in many places. The opening of the Sonora branch of the Atchison, Topeka & Santa Fe railroad has had much to do with this mining revival in the Santa Ritas, giving as it does an opportunity of shipping ores at a profit which could not formerly have been made. Crittenden station, on the Sonoita, the point of shipment for the Santa Ritas and Patagonias, is a scene of bustling activity. New depot buildings, stores, saloons, blacksmith shop, etc., are being erected, and a lively town will doubtless be the result. Several car-loads of sacked ore were observed there, ready for shipment to the Benson smelter.

THE WORLD'S OBSERVATORIES.—Some interesting statistics of this public observatories of the world have just been published. Their number is 118; 84 being in Europe, 2 in Asia, 2 in Africa, 27 in America, and 3 in Oceania. Of the European observatories Prussia has 29, Russia 19, England 14, Italy 9, Austria 8, France 6, Switzerland 4, and Sweden 3; Spain, Portugal, Holland and Norway each possess 2, while there is only one in Greece, Belgium and Denmark. The most ancient observatory in Europe, and in the world is that of Leyden, having been founded in 1632; then come Copenhagen, founded 1637; Paris in 1667; and Greenwich, in 1765. The Moscow observatory is the oldest in Russia, dating from 1750. Prussia, now the richest country in the world in astronomical observatories, had none before 1805.

A SURE cure for impoverished blood, pimples, and sallow complexion, is Brown's Iron Bitters. It will produce a healthy color, smooth skin, and is absolutely not injurious.

Mining Regions of British Columbia.

Although British Columbia is not very far away from us in California, the miners here know little of the region, and the miners up there know little of our systems here. We have endeavored in this number of the MINING AND SCIENTIFIC PRESS to collate such facts as are of general interest concerning British Columbia and present them with a map, so that a clear understanding of the features of the province may be gained.

To use the words of George M. Dawson, whose several invaluable reports form the principal source of information on this region, and will be liberally drawn upon, "it may be said, without any exaggeration, that there is scarcely a stream of any importance in British Columbia in which the color of gold cannot be found." The gold discoveries made in 1858 led to a great influx of miners in that and the following year.

The annexed table shows the actually known and estimated yield of gold, number of miners employed, and average earnings per man from the year 1858 to 1881.

Year.	Am't actually known to have been exported by Banks, etc.	Add ½ more, estimate of gold carried away in private hands.	Total.	No. of Miners employed
1858	\$ 390,265	\$ 130,088	\$ 520,353	3,000
1859	1,211,304	403,768	1,615,072	4,070
1860	1,371,410	557,133	2,228,543	4,400
1861	1,999,589	666,529	2,666,118	4,200
1862	3,184,700	1,061,560	4,246,260	4,100
1863	2,91,848	933,962	3,755,850	4,400
1864	2,618,404	872,801	3,491,205	4,201
1865	1,997,580	605,526	2,603,106	2,982
1866	1,800,651	639,217	2,439,868	2,644
1867	1,779,729	593,243	2,372,972	2,390
1868	1,331,234	443,744	1,774,978	2,300
1869	1,062,717	334,239	1,396,956	2,348
1870	1,349,580	440,860	1,790,440	2,450
1871	1,208,229	402,743	1,610,972	2,400
1872	979,312	326,437	1,305,749	2,300
1873	1,383,404	461,154	1,844,558	2,868
1874	1,800,651	639,217	2,439,868	2,644
1875	1,339,056	446,062	1,785,648	2,202
1876	1,206,130	402,464	1,608,594	1,960
1877	1,062,070	352,534	1,414,604	1,883
1878	1,062,070	352,534	1,414,604	1,883
1879	1,062,070	352,534	1,414,604	1,883
1880	844,840	281,971	1,126,811	1,955
			\$46,140,889	

These statistics are from official sources at British Columbia. The statistics of the last two years, compiled by Mr. Valentine, of Wells Fargo & Co's express, are as follows: For 1881, \$872,600; for 1882, \$671,845. This makes a total product of \$46,685,334.

The gold yield there shows a fluctuation year to year, which is due not only to the uncertainty of the deposits worked and number of miners employed, but also depends on climatic conditions.

The very general distribution of alluvial gold over the province may indicate that several different rock formations produce it in greater or less quantity, though it is only where coarse or heavy gold occurs that the original auriferous veins must be supposed to exist in the immediate vicinity of the deposit. "Colors" travel far along the beds of rapid rivers, and the northern and other systems of distribution of drift materials have, no doubt, also assisted in spreading the fine gold.

Gold Formation Proper.

The gold formation proper, however, consists of a series of talcose and chloritic, blackish or greenish-gray slates, or schists, which occasionally become micaceous and generally show evidence of greater metamorphism than the gold-bearing slates of this State. Their precise geological horizon is not yet determined, no geological survey to that end having been made; but Dawson is inclined to believe that they will be found to occupy a position intermediate between the more distinctive members of the Lower Cache creek group of Selwyn's first provisional classification of the rocks of B. C. (Rep. Prog. Geol. Survey, 1871-72, p. 61), and the base of the overlying mesozoic rocks, called in Dawson's report for 1878 the porphyritic series. If this be so they are probably the geological equivalents of some of the richest auriferous rocks of the State. By the inundation of the auriferous veins traversing these rocks the gold has been concentrated in the placers.

The greatest areas of these rocks appear in connection with the disturbed region lying next to the Rocky Mountain range, known in various parts of its length as the Purcell, Selkirk, Columbia, Cariboo, and Omineca ranges. Other considerable belts of auriferous rocks, however, probably belonging to the same age occur beyond the region, as in the vicinity of Anderson river and Boston bar on the Fraser; at Leech river, Vancouver Island and elsewhere.

The Cariboo District.

Discovered in 1860, has been the most productive and permanent. The 53d parallel of latitude passes through the center of the district, which has been described as a mountainous region, but is rather to be regarded as the remnant of a great high-level plateau, with an average elevation of 5,000 or 5,500 feet, dissected by innumerable streams, which flow from it in every direction, but all eventually reaching branches of the Fraser river.

As in all new gold mining districts the shallower placer deposits and gravels in its present stream courses first attracted attention, but with the experience of California and Australia, it was not very long before the deep diggings were found to be by far the most profitable. Williams and Lightning creeks yielded the greater part of the gold. The old stream courses of the Cariboo District pursued much the same course as their present representatives follow, running back across but never leaving the old valley, or running across the modern drainage system as is so often the case in the deep placers of California and Australia. There are many other localities in the district, which many believe would prove rich in the deep ground if properly prospected.

Auriferous Rocks.

In most gold bearing countries, the placer mines though often rich, have eventually led to the mining and treatment of the auriferous quartz from which the alluvial gold has been denuded. In British Columbia the alluvial deposits have thus far absorbed the mining energy of the country, but in view of the diminished yield of the best known placers, and the inevitable more or less complete exhaustion of deposits of this kind, attention should be turned soon to the quartz mines. Though much of the gold accumulated in the beds of old streams may have been derived from veins too small to work individually, it seems to scarcely admit of a doubt that in a region where so large a quantity of gold has been maintained within so small an area, rich lodes will be discovered and worked. Vein mining once initiated, Dawson thinks, will rapidly develop.

The districts of Kootenay, Omineca, and the Cassiar region, situated in the same belt of auriferous rocks, in the main features of their deposits resemble those of Cariboo. There are also several other localities in the line of the main development of the auriferous rocks, which have from time to time attracted attention and yielded more or less gold, but from their inaccessible position, limited character, poor pay, or depth of cover, they have been abandoned or allowed to fall into hands of Chinamen.

The greater part the gold range, especially towards the north, is very densely timbered and covered with moss, partly swamp and tangled vegetation, rendering its examination very difficult, and the discovery of the rich spots a matter requiring time and labor. In this respect it differs altogether from the character of ground that prospectors work in this State.

Cassiar.

Most miners will remember the Cassiar excitement of a few years since. The country was rather a disappointing one, and what California miners went made little by it. This is the most northern discovery on the auriferous belt in British Columbia, being situated about north latitude 59°, and separated from Omineca by over 300 miles of rough country, unknown geographically, and scarcely prospected. Gold has long been known on the lower part of the Stickeen river, by which Cassiar is approached by the coast; but it runs there in light, scaly particles, like those found in many places on the Fraser.

The deposits of Cassiar lie on the sources of the river Dease, and about Dease lake, the upper end of the latter being separated by only a few miles of low country from a part of the Stickeen. The Dease empties into the Mackenzie and this passes into the Arctic sea. The gold field is about 300 square miles. Dease and McDame creeks, the most important, are 100 miles apart. Discoveries have been pushed northward and eastward on river systems connected with the Dease, to an estimated distance of 370 miles in a region which probably lies beyond the province of B. C., in the Northwest Territory. The Cassiar mines are worked under great disadvantages. Situated in almost Arctic climate, where the soil is permanently frozen at a small depth below the surface on

the shady sides of the valleys, and a short season during which floods are liable to occur; a country difficult of access; high prices of provisions; only the highly auriferous character of some parts of the region make it at all attractive. The existence of these rich deposits are important as showing the continuity of the auriferous belt of the country.

It is scarcely necessary for us to refer to any length to the Fraser river gold deposits, the first to attract notice, but rich in only a small portion of their extent. Most early Californians will remember the great Fraser river excitement which took thousands from the mines of this State and nearly depopulated many of our towns. It was thought a second "49" was at hand. The gold occurs all along the course of the Fraser, but the mining is now done mainly by Chinamen and Indians.

In Vancouver Island, Leech River district, about 20 miles from Victoria, attracted attention at one time, and yielded considerable gold from a small area. Gold in small quantities has also been found in other parts of Vancouver Island, but the forests are so thick, little prospecting is done.

Where Gold is Found.

Gold has seldom been found *in situ* in the southern portion of British Columbia, but occurs in remunerative quantities in placer deposits in a number of places. These are generally found to lie on, or in the immediate vicinity of certain black, slaty rocks, from quartz veins traversing which the alluvial gold appears to be derived. In the search for gold placers, the extent and distribution of these slaty areas consequently become important, and though only a portion of the streams flowing over these slaty regions hold gold in paying quantity, a knowledge of their position may serve to deter too great expenditure of time in prospecting places probably barren, and turn attention to regions which promise better. These slaty rocks are those which have frequently been referred to by Dawson as included under the Anderson river and Boston bar series of the preliminary classification.

On the lower part of Fraser river, embraced in the district under discussion, no important gold-yielding bars or benches can now be mentioned, though this was the first region to attract the attention of the gold miner to B. C., and yielded largely in the earlier days of gold excitement. Here it would appear as the result of mining that the richest bars, and those yielding the heaviest gold, were found precisely in that part of the river which is occupied by the slaty rocks previously mentioned. The rapid character of the river has, however, led to the distribution of the finer particles of gold throughout its entire course. No deposit of any great extent, as rich as those at first worked on the Fraser, is again likely to be found, as the valley is generally quite narrow, and the upper benches, as well as the bars near the level of the stream, have been well prospected. A considerable quantity of gold is, however, still obtained from the Fraser, when the water is at a low stage, for the most part by Chinamen and Indians. It is also probable that the California hydraulic method may be applied to many of the benches with profit.

From the Thompson, near Nicommen, the first gold known to have been found in B. C. was brought (in 1857), and this locality has continued to yield a considerable quantity of gold at its lowest stages of water. The gold is in large particles, and is obtained by the Indians in crevices among and beneath the stones in the river. No rocks of the slaty series are known near this place, or for some distance above it. Mr. Alfred G. Lock, in his recently published valuable work on "Gold," where these facts are summarized, thinks "it is not improbable that the gold may here be derived from some of the igneous rocks of tertiary formation. The occurrence of gold in rocks of igneous formation in such quantities as to produce paying placer deposits has lately been distinctly proved in several cases in other parts of the world, and should be borne in mind." On the Nicola river gold in thin scales has been found for about 18 miles above its confluence with the Thompson.

Tranquille river flows into Kamloop lake; was worked before 1862, and has afforded occupation to a varying number of miners every year since. It has almost entirely fallen into the hands of Chinamen now.

On Louis creek, in the lower part of the North Thompson, gold mines have been worked.

On the South Similkameen, a short way above Vermilion forks, gold mining has been carried on for several years, though now the Chinese have possession. The Tulameen or north fork of the Similkameen, though yielding "prospects," has never given remunerative employment. Further down the Similkameen gold has been found in a few places, notably at Twenty-mile creek, where it was worked for some years. Gold in small quantities has been found in several streams flowing into the Okanagan valley, but few mines of any importance are there. The best deposits of Mission creek have been worked though the high benches may pay for hydraulic. Cherry creek, a tributary of the Shuswap river, still gives employment to a few white miners and a number of Chinamen. Scotch creek, flowing into Shuswap lake from the north, has yielded some heavy gold, but no mining is now going on there.

In the Queen Charlotte Islands no alluvial gold seems to have been found, but auriferous quartz exists in some quantities.

Other Localities Yielding Gold.

The map which Mr. Patterson has prepared for us for this edition of the MINING AND SCIENTIFIC PRESS, shows the various streams, as much in detail as the scale would admit, but of course many of the smaller ones could scarcely be shown. Still a very good general idea of the country is given. The following is a summarized list of the localities in British Columbia known to yield gold, with notes of their present condition so far as can be gathered.

Cariboo District.

Williams Creek and its tributaries—McCallum's gulch, Walker's gulch, Mink gulch, Grub, or Black Jack gulch, Stout's gulch, and Conkling's gulch. McArthur's creek, worked out for drifting and no hydraulic work in progress. Lowtree creek, some good ground being still worked; water scant for hydraulic. Jack of Clubs creek, all deep work, gravel being 150 feet deep near the mouth. This creek is a favorite among those which are considered yet unprospected; the impression prevailing that an old channel exists which has not yet been found.

Creeks entering Willow river are as follows: Mosquito creek and Red gulch, worked out for drifting but paying by hydraulic; Whipsaw creek; Sugar creek; Grouse creek, deep ground worked out; Antler creek, Chinamen working on benches; Pleasant Valley, never bottomed or much prospected, but might be embraced in a scheme for draining Williams' creek; Bear and Swamp creeks, in good pay; Cunningham creek, a crevice with 600 ounces of gold was once found here, several hydraulic claims at work in successful attempts to reach the deep ground; Harvey's creek, first gold in paying quantity in the Cariboo district was found here in 1860.

Creeks on the north side of Cariboo lake: In Nigger Pine and Goose creeks small quantities of gold have been found; Keithly creek; Snowshoe creek, east branch deep ground not prospected; Duck, Black Bear, Cedar, Harzeline, Moorehead, French, Canadian, Canyon creeks, and Quesnelle and Swift rivers, are all in this region.

The chief tributaries of Lightning creek are: Amador, Van Winkle, Chisholm, Last Chance, Davis, Anderson and Jawbone creeks. There are many quartz veins, but so little has been done on them it is scarcely worth while enumerating them.

In Cassiar District are the following localities where gold is found: Stickeen river, nearly exhausted; Dease creek probably yielded \$700,000; Thibert's creek, part still paying; Brady creek; Eagle river; McDame's creek, the work important in the region, being worked in several places and will yield for some years largely; Snow creek, bench diggings still mined extensively; Quartz creek and Rosella creek worked out nearly; Dennis, Patterson, Gold and Slate creeks; Somer's creek, number of tunnels being worked; Spring creek, De Leard river and Rapid river.

In Omineca district are several creeks but not many mines working. The same is the case in Kootenay district. The Great Bend country is now almost abandoned.

Other Districts

The Parsnip river, draining the Omineca country, has proved remunerative in several localities. The bars on Findlay river yield, but

headwaters have not yet been prospected. The Fraser river we have previously spoken of. McLennan creek does not pay. Nechaco river shows colors; same with Chilaco river; Chilicotin river, some gold near mouth. Bridge river has heavy gold. Lilloet river, flowing into Harrison Lake, has some gold. South and North Thompson rivers show gold. Among other gold-yielding streams, are Scotch creek, Main river, Thompson, Anderson river, Coqui halla, Nicola, Bompante, Horsely, Skagit, Similkameen, Okanagan, Kettle, and Lower Himathio rivers, and Hat, Mission, Rock, Boundary, Seymour, and Prospect creeks.

On Vancouver's Island, Leech river has proved auriferous for four miles of its length. The rich ground is exhausted, but the banks of drift and cement might pay for working by hydraulic method. Sooke river, Goldstream brook, Jordan and Nanaimo rivers all show some gold.

The annexed table shows the condition of the auriferous industry in British Columbia in 1880, which is as far as full statistics are procurable. It is noticed that no quartz mining is mentioned, and but little is carried on.

NAME OF BAR, GULCH, CREEK OR RIVER.	Companies Working.	Men employed in Season.	Estimated value of gold for the year.	Total.
CARIBOO.				
Barkerville Division:				
Williams' Creek.....	25	99	\$79,000

				45,800
Totals.....	373	1960	\$386,630	

Of the companies working, shown by number in the table, 271 were getting gold and 28 prospecting. Of the whole 373, there were 3 bar claims, 178 creek claims, 50 bench claims and 83 hill claims. Of all these, 21 were worked by rockers, 205 by sluices, 41 by hydraulic, 25 by shaft and 21 by tunnel.

Tramps.

With the warm days and beautiful weather, comes the old complaint from all parts of the country of annoyance from tramps, and a revival of the question, what shall we do to check this stream of able-bodied vagrants and bummers. The tramp is a very old stager in the world, and his footsteps may be traced along the ages from the vigorous laws enacted against his vagabond habits and ways; and old statutes, as far back as the fourteenth century, denominate them "able-bodied, sturdy and valiant beggars," and prohibited any one of this class begging of the town where he had last resided for three years, as this would diminish the number of impostors by limiting their tale of woe to ears that could know how true or false it was. A statute of Henry VIII whipped the "sturdy and valiant beggar" for the first offense, cut off the tip of the right ear for the second, and for the third transgression he was liable to be indicted for wandering, loitering and idleness, and put to death as an enemy of his country. During the reign of Elizabeth, the penalty was reduced to a long service in the galleys, or banishment on pain of death if they returned. We give these citations from an old statute merely to show how formidable the question of trampdom looked in an early day to all friends of good government.

What should be the attitude of the State or municipal legislation upon this subject, may require the long and patient study of our wisest minds to reply. An old code in a harsher age may whip, maim, burn and banish the vagrant, but our milder and more humane civilization, should be as eager to save the idle and reform the vagabond, as it is to educate the ignorant and reclaim the thief and drunkard.

But one thing is clear, that feeding the able-bodied tramp at the back door of our homes, or preparing free lunches and soup houses for the idle classes of our cities, or giving them money, is no part of a wise and judicious system of benevolence; unless a pestilence or a fire, flood or earthquake creates a temporary demand for that form of beneficence. Idleness and trampdom breed vice and crime, and whoever out of a soft-hearted charity feeds this class helps to foster a greater evil.

It is also clear that it is the first duty of the government to protect the good and industrious citizen from this army of idlers, strolling vagrants, and lazy, dirty loafers who now infest the land, and render home an unsafe place for life, virtue or property. The home in the country is no longer the castle where the mother and children feel safe when alone, but has become a place where the sight of a rough lout along the road, or hanging around the premises, creates a boding fear, and fills the night with terror. He must be fed and lodged, not from a feeling of tender charity, but from the timid apprehension that if turned away he may burn the house, barn or grain stack, or in some other violent way seek revenge for the non-payment of the tax he levies. Now, a proper regard for the social welfare and civilization will love and protect their homes more than it will the personal liberty of the tramp; and, hence, out of regard for the public good, and also for the welfare of the vagabond, will desire some means of promptly putting a stop to his prowling and wandering about the country, or burrowing in the city, and compel him to learn the pursuits and habits of industry. A philanthropy which feeds these swarms of idlers and vagrants, hummers and old sots, and which forgets the sacredness of all the homes in the country and towns and cities, is not a charity worthy of the least respect. It may quote its usual platitudes about casting bread upon the waters, harboring angels in disguise, and the like, but it is merely a form of charity that hatches serpents' eggs, and that may turn into rapine and murder.

Then we owe a duty to the morals of the present and future. Each adult beggar may be training a family in vice. This is especially true of the idle and mendicant classes about our large towns and cities, who often send their children in rags and dirt, with well-practiced lies upon their lips, and the charity which helps to feed these paupers helps to increase the statistics of vice and crime with the advancing population. In Italy and Spain, where the rich and well-to-do have been in the habit of scattering coin among the lazzaroni for centuries, the streets and roads swarm with beings who

never think of doing a day's work. Tramps begot tramps, and out of the realm of trampdom comes a harvest every year of lazy loafers, drunkards, pimps, hawds, hoodlums and criminals.

There can be no doubt that the chief cause of trampdom is laziness. Man seems naturally averse to work. Industry, like learning or a taste for the beautiful, is an acquired virtue. It is a cultivated plant, and not a weed. All savage people are lazy. They will not stir themselves, only to get a little food, and, once gorged, seek sleep and idleness. And hence, as the streams of beggars and tramps flow from the swamps and bogs of indolence, stupor, shiftless habits and lack of ambition, it has been suggested that it might be at least a partial remedy to provide in every city and county, or a group of counties, a farm, and shops for all kinds of work, where the idle could find employment at reasonable wages, and where the tramping vagabond should be compelled to labor for his own support, and perhaps acquire habits of industry. There may be no feasibility in the suggestion, but there can be no doubt about the fact that such beggars and bummers as we have described are public nuisances, and should in some way be removed from society. A century which has brought so much light into the world ought not to be baffled by this problem, and let this evil grow till it curses our land like some of the fairest portions of Europe.

NEGOTIATIONS are now pending for the sale of a group of 11 mines in the Swisshelm mountains, Carlisle county, Arizona, belonging to Adam Clark and J. W. Fleming, of this city. The claims are reported as being extraordinarily rich; the lowest assay yet made from the ore on the dumps, of which there is about 300 tons, runs 64 ounces in silver. The district is well watered and is covered with excellent wood.

A FISH of solid gold, of the value of \$2,500, is reported to have been dug up in Ober-Lausitz, the border land between Saxony and Silesia. Its surface is said to be incised with mythological figures, wrought after archaic Greek patterns.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY C. HANES, State Mineralogist.]

The Patio Process.

(CONTINUED FROM PAGE 187).

25 a ton, making a difference of \$2.58 a ton in favor of the hacienda driven by water power in the way that I have described.

Advantages and Disadvantages.

The only positive advantage of the patio process lies in the cheapness of the plant. Rough stones and hydraulic lime for tanks, washers and tahonas are procurable almost anywhere. Timber for the woodwork is also generally plenty; no elaborate carpentry is needed; and with a rawhide or two for thongs the outfit is complete. In no other country than Mexico would such a process have taken root, and only the richness of the mines and the want of transportation have enabled it to survive even in that most conservative land.

Some of its disadvantages are the constant bother, to say nothing of the expense, in working with mules, and the frequent banding of the ore, quicksilver, and amalgam, which besides being expensive, gives excellent chances for robbery. There is a great waste of materials, and of quicksilver, gold and silver. Large quantities of tailings are produced, which must be concentrated and shipped, with extra expense and with loss of interest on a considerable amount of capital. Last, and very far from least, is the great disadvantage of time; four weeks, at least, are needed under the most favorable circumstances, from the arrival of the ore at the hacienda until the extraction of the silver, and this time may be greatly lengthened, or even doubled, by variations of weather and of temperature. Even the Mexicans are beginning to be alive to these considerations, and it is probable that in a decade or two the patio haciendas now in operation will be memories of the past.

In the consideration of this process I have made no effort to investigate its reactions. Several learned chemists have, I believe, written on this branch of the subject, but I do not know that they ever approached an agreement. I may well be excused from entering into a discussion which has already proved itself so very unprofitable.

Accompanying this paper I give a scheme of the patio process (see engraving), from which the relations of the various products can be readily seen, and also drawings of the apparatus used.

The Mexican pound has 16 ounces, and weighs, according to the tables of the Durango mint, 0.46024634 kilogramme. This is the weight referred to in the preceding paper wherever the word pound occurs; the ton is 2,000 of these pounds. The "marc" used in Mexico as a unit in weighing silver and gold weighs eight ounces, or half a Mexican pound.

INDIA-RUBBER OIL.—Dr. Beckhart, of Spandau, has patented in Germany an india-rubber oil which is intended to serve as a protective against rust. According to the description published in the German technical press, the rough oils obtained in the dry distillation of brown coal, peat, or other bituminous substances, are subjected to further distillation. Thinly rolled india-rubber cut into small strips is saturated with a four-fold quantity of this oil, and is let stand for eight days. This mass, thus composed, is subjected to the action of vulcan oil, or a similar liquid, until a homogeneous, clear substance is formed. If this substance is applied in as thin a layer as possible on a metal surface, it forms, after slow drying, a kind of skin which ensures absolute protection against atmospheric influences. The durability of this covering is said to be most satisfactory. India-rubber oil is also said to be effective in the removal of rust which has already been formed.

The Germania White Lead Works have begun to discharge lead. The works have been operating about two weeks, and the samples of white lead taken from the oxidizing cylinders yesterday were very fair, being much finer than was anticipated for the first manufacture. They expect to produce fine lead for painting from the granulations in the small space of 10 days. Under the old system it required from three to five months to produce good color. The company will begin grinding lead with oil this week and packing in kegs ready for the market. The enterprise has proved a success already in producing a good article at small expense, and we trust will prove a great financial success.

A LARGE body of high grade ore has been struck in the Monitor and Gore, in Taylor District, Nev. Two drifts have been run just inside the boundary lines of each claim and both are in ore, top, sides and bottom. The drifts start from a point common to both, but diverge, one going into the Monitor ground and the other into the Gore. This new strike is well calculated to brace up mining property in Taylor District at a time when it does not stand particularly in need of it. Taylor is one of the few mining districts that is destined to come to the front on its own merits.

A NEW artificial ivory of a pure white color, and very durable, has recently been manufactured by the inventor of celluloid; it is prepared by dissolving shellac in ammonia, mixing the solution with oxide of zinc, driving off ammonia by heating, powdering, and strongly compressing in moulds.

COMPOSED of the best known tonics; iron and cinchona, with well known aromatics, is Brown's Iron Bitters. It cures indigestion, and all kindred troubles.

BROWN'S
IRON
BITTERS

will cure dyspepsia, heartburn, malaria, kidney disease, liver complaint, and other wasting diseases.

BROWN'S
IRON
BITTERS

enriches the blood and purifies the system; cures weakness, lack of energy, etc. Try a bottle.

BROWN'S
IRON
BITTERS

is the only Iron preparation that does not color the teeth, and will not cause headache or constipation, as other Iron preparations will.

BROWN'S
IRON
BITTERS

Ladies and all sufferers from neuralgia, hysteria, and kindred complaints, will find it without an equal.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address,

ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco.

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 26, 1883.

Mr. A. B. Paul:—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quicksilver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which slides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them.

B. G. McLAIR,

Superintendent Indian Spring Drift Mine.

Scientific, Mining and Other Valuable Books.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL.

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams, 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver, 1880.

This rare book on the treatment of gold and silver ores without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00, colic, postage free.

How TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established. Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

The Coming Eclipse of the Sun.

Early Preparations Required for Its Observation.

EDITORS PRESS: A total eclipse of the sun will occur May 6th, but will only be visible at the Marquesas Island, and at Tongataboo and Eoa, Pacific ocean. This total eclipse should be of considerable interest to the whole scientific world, as well as amateurs, for the unusual opportunities it may present for the successful determination by scientists of all the interesting phenomena that an eclipse of such long duration can best afford. I believe it has been computed by astronomers that the total phase will occupy about six and one half minutes, which is fully twice as long as the average of total solar eclipses. Of course, the value of photography and analytical observations by the spectroscope, can hardly be over estimated, and in general, affords the chief attractions to the best scientists from every nation. It is well known, also, that every observer has his special work, and however interesting the prospect may be for new discoveries in another branch of phenomena, it is absolutely necessary for such a specialty to be provided for beforehand, that ample justice may be done in the matter; for the limited time at best, that a total solar eclipse affords for the several phases of observations. I shall not attempt any general description of the value of observations of total eclipses of the sun, for the public are perfectly familiar with the subject from scores of illustrated volumes, but the rare opportunity of special observations for an

Intra-Mercurial Planet,

However discouraging it may seem to have proved hitherto, is deserving of the best encouragement, and I would like to suggest that every Government would do well to prepare a fine Vulcan medal, which might, in honor to the memory of Leverrier, who labored so assiduously to determine an orbit for one or more of the suspected Vulcans, be termed

The Leverrier Medal.

It should be, of course, a very handsome and valuable gold piece; but it might be still better for different nations to give different rewards—some works of art of practical value, such as a good working, achromatic telescope, not less than six inches aperture, properly mounted, spectroscopes, and photographic apparatus, etc., of the best make. Each Government, should any present it, upon proof being made of the discovery of an intra-mercurial planet, and the first computer of its orbit, should be entitled to a similar reward or rewards from each country. Any computations that may have assisted in making the discovery should likewise be duly rewarded.

It seems to me to require some stimulating arrangement of the kind to stir up a general interest in the matter. I cannot hope to be an observer myself, but having given considerable attention to the inquiry for several years, and having great faith in Prof. Watson's re-observation at Wyoming, July 29, 1878, I think it very possible that an approximate orbit may now be determined, which way, perhaps, be verified at the forthcoming eclipse, or, if not, still materially aid to the re-discovery May 6th next, and the determination of its period in future. Assuming then, that Prof. Watson, July 29, 1878, saw Vulcan at apparently 2° 9' from superior conjunction, I long ago explained that that distance was equivalent to 11-24 of a revolution, and indicated 1,808 11-24 apparent revolutions from January 1, 1750 to July 29, 1878, each revolution being 25.96825104 days, or 25d. 23h. 14m. 17s., and was the nearest approximation, I believe that could be found. Gaictat's adaptation of the Leverrier formula of the case, which he failed to see, could be applied to the planet being in the superior part of the orbit, and which was roundly called 26 days. Now, then, assuming that period continued to May 6th next, gives us 67 1-11 revolutions, or about 13-24 from the last inferior conjunction, or say about 2° 9' to 3° past the other side of the sun. Early in September last I made some comparisons of an orbit derived from Prof. Balfour Stewart's sun spot theory. The period would approximately be 25.69826 days, taking 67.8 revolutions nearly from July 29, 1878, putting the planet any 3° of the orbit past its first elongation, so apparently at the best position 10° 12' from the sun.

Although the two computations point to those particular positions more particularly, it is, of course, of the utmost importance that the entire range of east and west elongations should be swept by the fieldglass, and very carefully scrutinized, as we have no absolute data to compute the position as required. But again, in the event of the true period being nearly in accordance with Leverrier's 33.0225 sidereal periods, or about 36.3 synodical periods, there would have been just about 48 apparent revolutions since July 29, 1878 by May 6th next, so that the planet would again be very nearly the 2° 9'. Prof. Watson saw it from superior conjunction. Thus, we have some points that may help the matter, and in case of verification of either would be peculiarly interesting.

I will now say a few words about locality. Inconvenience will not be regarded, of course, by those scientists who determine to make the best of the unusual opportunity, and it will certainly be the more to their credit. It is certainly a much shorter and less expensive trip from California than from the eastern States or

Europe. Still some of the best eastern and European astronomers and scientists will doubtless be on hand where they hope to obtain the best observations. The choice lies between the Marquesas about W. longitude 140° 41' and latitude S. 7° 50' to 10°, or possibly Tongataboo, and Eoa, southeasterly about 10 miles, and rather south of the Friendly Isles. Tongataboo is considerably the largest island and lies about 174° to 175° W. longitude and about 21° S. latitude. It is doubtful whether it is quite within the belt of the total eclipse or whether Eoa is more favorably situated. Possibly both may be included if the belt is 2° wide, as may be seen in the *American Nautical Ephemeris*. There are interesting accounts of both islands in the "U. S. Exploring Expeditions," Vol. 23, by Capt. Wilkes, 1840-42. Probably merchants have been much better acquainted with the islands since that time. Eoa is about 30 miles circumference, and rises to 350 feet in height. It was chiefly volcanic, without much space for cultivation, as supposed in 1840, and very few inhabitants, while Tongataboo had a large population then, and has a good harbor, but rather difficult of access. The best illustration I have seen of Tongataboo is in "Capt. Wilson's Voyage, 1796-8," scale, five eighths of an inch to one mile, making a good quarto-size map, showing the island, coral reefs, and channels, etc. The Marquesas are, of course, very much nearer to America, and only about 30° SSE. of the Sandwich Islands. The two most northerly of the islands are apparently well within the total eclipse belt, but, having failed to find a chart of them in detail, I cannot give their names or size of those within the total eclipse belt. Mr. Ellis' "Polynesian Researches, 1853," gives an interesting account of the group. He says the Marquesas form two clusters. The southeastern comprises five islands—Tahuata, Hiraao, Mahotane, La Magdalen and Hood's Island. These were discovered in 1595, but the north cluster not until 1792. This division consists of five islands, also: Nukahira, the largest, Mapan, Trevenian's Island, Huakuka, Hogert Rocks, and Robert's Island. The men are a fine race, but warlike, licentious and fierce, and not cured of cannibalism, but may be improved now.

A. F. GODIARD.

Sacramento, March 6, 1882.

Home Manufactures.

All history will vindicate the statements, that exclusively mining and agricultural countries are usually poor and dependent, that the production of the raw material from the fields, forests or mines is not the productive wealth that builds up towns and cities, of at least the kind that most greatly benefits the trading and wage-receiving classes. It is a kind of wealth which stands in pools, and does not spread out over the whole country and make the wilderness and solitary places glad, and the deserts rejoice and blossom as the rose. It does not thrill and electrify the social, educational and material interests of the country so thoroughly as to cause all parts to pulse with life and health. The reason is obvious. The raw, bulky, heavy material goes abroad at low rates, and returns as the product of skilled labor, at high rates. The difference between the price of the two commodities is the loss sustained by the non-manufacturing producer, and no people can claim to be well on the way to the highest prosperity who are content to be vegetable dealers and marketers, the producers of raw material, wholly dependent upon the capricious and fluctuating prices of the foreign purchasers and manufacturers for the necessities and comforts of life.

We study the future in the light of the past, and what home manufactures have done for other nations and States, we may safely calculate they will do for California. We need only the example of our English ancestors. Though England is first known in history by the efforts of the Phœnician navigators to obtain the products of her mines, and although her pastoral and agricultural wealth chiefly attracted the Roman conquerors, still England never emerged as a first-class power in Europe until she had learned to manufacture her own productions. Then the island became a busy hive of industry and wealth. England exports no raw material; and what is the consequence? The whole land shakes with machinery, and her sea coast is one long counter, where she trades with the world, buying the crude material and selling the refined and putting the difference into her pocket. Home manufacture has largely been the recuperative power of France, Prussia and Holland, after being prostrated by long, devastating wars. These countries have steadily grown rich—have money to loan and invest in great public enterprises—while Russia, whose exports consist chiefly of the raw material, is one of the poorest nations of Europe, considering her extent and resources. Home manufactures made New England, with her thin soil, granite hills, and rough climate, rich and self-reliant; while the sunny South, with a fertile soil, a delicious climate, but exporting all she raised, languished in poverty. But the claim of a new era of prosperity in that fair clime is evidenced by the fact that her capital is beginning to whiz and whirl in her looms and spindles.

We need only study what the mining products, the coal measures, and a system of careful agriculture combined, have done for the political and material prosperity of Great Britain, to learn where the great secret of California's future prosperity lies if duly appreciated.

There is no State in the Union that possesses so many marked advantages for building up a large manufacturing industry. We have wood, coal and petroleum in abundance. The out-door laborer rarely suffers from heat or cold. The ice never pinions the mill wheels, and the path to the shop or factory is never blocked with snow. Then, nearly all the staples, which constitute the same material, can be produced with the greatest ease, and in the largest quantities. The soil and climate are adapted to an almost endless variety. Anything in the line of wool, grain, wool, cotton, silk, California can produce of the best quality, and as cheaply as the most favored country in the world. There is no reason, then, why we may not manufacture, at least four fifths of our present importations, and lay the foundation of an export trade, that will whiten the Pacific with the sails of our commerce.

There is already a great demand for our woolen goods, many mills reporting it impossible to fill their orders, and yet the bulk of the wool crop is still shipped east. Last year, California flour went to Great Britain, Germany, China, Japan, Central America, Australia, British Columbia, Mexico and the Pacific Islands, and everywhere at good profits to the shippers, and yet, the most of our wheat still goes in the sacks to foreign countries. Now, any portion of this raw material which we can manufacture to export, is just so much more added to the wealth and prosperity of the State.

Home manufactures made England the richest and most powerful nation on the globe! Home manufactures made New England the leader of a mighty republic! And home manufactures may make California the commercial empire of the Pacific coast.

DON'T FORGET THE STAMP.—Always take a last look at a letter before posting to see that the stamp is in place. Recently one of our agents in Los Angeles county found a letter containing \$3 for one year's subscription to our paper, held for postage which the writer no doubt thought he had duly stamped, and but for the incidental finding of it by our agent, would of course have supposed we had received the money at the proper time. Let all subscribers when remitting or ordering their paper stopped be sure they duly stamp their letters.

Be Fair.

If there are any more subscribers (who are able to pay) receiving this paper, who have not and do not intend to pay for it (if they can avoid it), they are earnestly requested to notify us by postal card before their indebtedness further increases. We do not wish, and never have intended to send the paper to a single person who does not want it, but, when sent in good faith to a subscriber on our part, we cannot afford to be cheated out of our honest dues, and shall not if we can, by fair and legal means, prevent it. We are ever ready to allow for any real mistake on the part of any one, but we have little confidence in the good faith of any man who will receive the paper month after month with the deliberate intention of not paying for it, when three minutes' writing and a one cent postal card would stop it.

A Cheerful Recommendation.

BENICIA, CAL., February 4, 1883.

Messrs. Dewey & Co., Patent Solicitors:—I am in receipt of my patent, "Improvements in Vehicle Brakes," obtained through your Agency, and would say I am much pleased with thorough and graphic description in specifications and drawings, and can cheerfully recommend you to anyone wishing to obtain favors in your line.—Truly yours, C. R. DUNN.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The Press gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 252 Market St., San Francisco, Cal.

CURIOUS EFFECTS OF LIGHTNING.—Some interesting effects of lightning have been observed by M. Allard at the summit of the Puy de Dome, where, on a circular tower, is an iron mast about 20 feet high, supporting an anemometer of the Robinson type, with four copper cups. There is also a ladder and stand (both made largely of iron), to allow of access to the anemometer for cleaning. Two metallic cables connect the system with the copper plates in the ground. Under these conditions, St. Elmo's fire often appears at the salient points of the mast, stand, etc., and a slight hissing is sometimes heard. All the cups of the anemometer show numerous signs of fusion by lightning, and only in their upper half; their connecting iron circle has also been fused in some places. Wherever such fusion has occurred, the metal has been raised like a small volcanic cone in the center of a crater. Some exterior attractive force seems to have raised the melted substance. M. Allard proposes to study the phenomenon more closely.

DETECTING COPPER IN FOOD.—It is well known that unscrupulous vendors do occasionally employ salts of copper to give a fine green color to pickles, but we incline to the opinion that this dangerous form of food adulteration is far less commonly practiced than is generally believed. To detect the presence of copper, we need only take one of the suspected pickles, cut it into pieces, then add some ammonia. If copper is present, even in very slight traces, the addition of a few drops of ammonia will instantly develop a beautiful deep blue coloration.

CURE FOR IVY POISONING.—Bathe the parts affected with sweet spirits of nitre. If the blisters be broken, so as to allow the nitre to penetrate the cuticle, more than a single application is rarely necessary; and even where it is applied to the surface of the skin three or four times a day, there is rarely a trace of poison left the next morning.

Esthetic Taste.

The growing culture and prosperity of the country is marked by nothing more strongly than the almost universal indulgence in decorative art. Homes, where once comfort alone was studied, beauty and grace are now considered to be of nearly as much importance. Furniture has lost its hard, monotonous and unsocial looks. The days of the pair-cloth sofas and six hair-cloth chairs to match, and which required the occupant to exercise no little skill in maintaining his equilibrium, have now nearly passed away and graceful shapes, suggestive of luxuriant repose, taken their places. The windows of nearly every cottage are cheaply, yet prettily draped; ceilings and walls harmoniously colored; books, albums, vases and pictures in profusion, and elegant what-nots tastefully crowded with bric-a-brac, where years ago a prim, stiff precision was the order of the day.

Even business is putting on stylish airs, and signs, letter-heads and business cards are rapidly becoming works of art. The successful job printer of the day must possess an eye for light and shade, delicate tints, and finish, nearly equal to the landscape painter. This development of a love for the beautiful indicates moral and intellectual advancement, and when it becomes so general and runs into such infinite detail, may be regarded as a sign of national progress. It is true, we have still a great deal of hideous caricature in the way of ornamentation. But even that is a good sign, for it is an instinct feeling for the light. The love of gaudy trinkets and loud colors, peculiar to savages and rude minds, is only a wild flower of human nature, that in time may be developed into a rose of rich beauty and fragrance.

Easy Binder.

Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable and so simple a child can use it. Price, size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Record, Home Journal, Harper's Weekly, and Scientific American, 75 cents; postage, 10 cents. Postpaid to subscribers of this paper, 50 cents. Send for illustrated circular. Agents wanted.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves.

Subscription rate, \$4 a year.
N. B.—Personal attention will be called to this (as well as other notices, at times) by turning down a leaf.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jacket, either Wrought or Cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALLIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,700 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Plain Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs., heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

 NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

GRAIN THRASHER AND CLEANER.—David H. Rader, of Gilroy, and Job Malsbury, of Hollister, Cal. Dated March 6, 1883. No. 273,391. This invention relates to certain improvements in machinery for cleaning and thrashing grain. Its object is to greatly increase the cleaning capacity, and to this end the invention consists in novel features of construction and combination and arrangement of parts, somewhat difficult to describe without the aid of engravings, but quite ingeniously constructed. The inventors call this the "Golden Monitor," and claim that it has double the capacity of any other grain thrasher and cleaner. The mechanism is reduced to the fewest parts, is of the simplest description, and is very easily driven.

GANG PLOW.—George Lissenden, Stockton, Cal. Dated March 6, 1883. No. 273,292. This invention relates to certain improvements in sulky or gang-plows; and it consists of a novel mechanism by which the plow-frame is connected with and supported upon the wheel-axes of a draft-pole and its connection with the plow, and of a lever, connecting-arms, and standards, whereby the plow may be raised out of the ground or let down to the proper depth. It also consists in means for connecting the pole with the frame of the plows, and an adjusting mechanism for its rear end, which is so connected as to travel forward and back with the pole with relation to the frame, together with the means for supporting the whole upon the wheels, by which the plows will hold their position in the land and make an equal cut in land of variable quality and hardness.

CAR BRAKES.—Edward M. Buckley and Andrew Jackson, S. F., Cal. Dated March 6, 1883. No. 273,345. This invention relates to certain new and useful improvements in automatic car brakes, and consists in an intermediate lever or bar, through which power is transmitted from the longitudinally moving draw-head, acting through a certain pivoted lever, to the braking apparatus. It also consists in a novel means for throwing these parts in and out of engagement when desired. The general object of the invention is to make the entire train brake itself through the draw-heads of each car; but the particular object of the construction here patented is to simplify the mechanism, whereby it may be furnished at small cost, and produce as effective results.

WASHING MACHINE.—William A. Hedger, Wheatland, Cal. Dated March 6, 1883. No. 273,359. This invention relates to the class of washing machines, and more particularly to those in which a hemispherical rubber is caused to oscillate in a concave board. It consists in a novel means for elevating and depressing the rubber to allow the insertion of the clothes and to press them down to their places. The object is to overcome that difficulty which is known to exist in introducing the clothes under a rubber which operates in a confined space and remains close to its board; and, further, to provide a means for easily adjusting the position of the rubber after the clothes are inserted.

BALING PRESS.—Henry Tyack, of Grass Valley, Cal. No. 273,407. Dated March 6, 1883. This invention relates to certain im-

provements in presses for baling hay, cotton, wool, rags, hops, hair, etc. These improvements relate to the entire press and all its parts, and include principally the construction of the body or frame, the follower and the means for operating it, the cover or lid and the means for adjusting and opening it, the front or discharge door and the means for mounting it, the side door, and other details. The object of the invention is to provide an effective baling-press, and each of the several improvements made has this general result in view.

WINDOW SASH AND FRAME.—Jacob Gruninger, S. F., Cal. Dated March 6, 1883. No. 273,355. This invention consists in a means for hinging the window-sashes in their frames, whereby, by the removal of the inside beads and a parting strip, both sashes may be swung to the inside. The object is to provide easy access to the outer surface of the windows, for the purpose of cleaning. When the sashes are fast in their frames, there is much danger in getting at the outside to wash the glass, and many accidents have occurred; but by swinging the sashes into the room, the glass may be washed on the outside with safety and convenience.

TWO-WHEELED VEHICLE.—Benjamin P. Whitney, Potter Valley, Cal. No. 272,177. Dated Feb. 13, 1883. This invention relates to certain improvements in two-wheeled vehicles, and these improvements consist in a means for supporting and hinging the seats at one side to the shaft, and latching it at the other, in certain draft irons or rods attached to the axle and to the foot board, and in breaking the hub of the wheel, and in a means therefor. The object of this invention is to furnish an easy entrance to and exit from the vehicle, and an easy-riding seat to transfer a portion of the draft from the side springs to the axle when a sudden jerk occurs.

AUTOMATIC CAR BRAKE.—Edward M. Buckley and Andrew Jackson, S. F., Cal. Dated March 6th, 1883. No. 273,344. This invention relates to a new and useful automatic car brake, and it consists in a novel combination of devices for connecting the spring drawhead with the braking apparatus, whereby the motion of the former, when it impinges against the opposite drawhead, is transmitted to the brakes to apply them to the wheels. The object is to make each car brake itself by its own momentum, to make the force of the brakes depend upon the momentum, so that the braking operation shall be entirely automatic, and to provide a simple, cheap and effective device for the purpose.

MACHINE FOR STRAIGHTENING OR BENDING RAILS.—Peter Fricchette, Sheridan, Cal. Dated March 6, 1883. No. 273,353. This invention relates to a new and useful machine for straightening and bending the rails of a railroad, and it consists in the details of construction and combination of devices, in combination with a frame having a central longitudinal passage, to which are directed the pressure ends of a number of screw-jacks extending through the top, bottom and sides of the frame.

TRACE-HOOK.—Calvin P. Wakefield, Cressey, Cal. No. 272,175. Dated Feb. 13, 1883. This invention relates to a new and useful improvement in trace-hooks, and it consists in a metal hook riveted to the trace and provided with a peculiar overlapping guard. The object of this invention is to prevent the other parts of the harness from getting into the hook and becoming entangled.

CAMERA SHUTTER.—David S. Boydston, Volcano, Cal. No. 272,117. Dated Feb. 13, 1883. This invention consists in a two-part shutter, mounted in suitable guides behind the aperture, and moving apart to open the camera, or together to close it, under the influence of springs peculiarly arranged and secured to the shutter. The object of this invention is to provide an easy means of opening and closing the camera with great rapidity, whereby difficult and instantaneous photography is assured.

COMBINED THIMBLE AND THREAD-CUTTER.—Washington J. Miller, Alameda, Cal. Dated March 6, 1883. No. 273,330. This invention relates to an improvement in a combined thimble and thread-cutter, and it consists mainly in the peculiar means by which the knife is secured to the thimble, so that it may be reversed and used as a seam ripper, and also in a channeled plate, which is fixed to the edge of the thimble, so that the edge of the knife is within the channel, and below the level of its sides.

LANTERN.—John Gillig, Virginia City, Nev. Dated March 6, 1883. No. 273,272. This invention relates to certain improvements in lanterns, and is more especially applicable to miners' lanterns, having a conical projecting top. It consists of bent lugs or hooks hinged to the lower part of the lantern frame, and capable of being turned inward to allow the glass to slide upward from the bottom into its grooves or guides, after which the hooks may be turned outward and serve to support the glass which is let down upon them.

MINES IN PRESCOTT, A. T., that were worthless two years ago, on account of being low grade, are now worth from \$10,000 to \$100,000 each.

News in Brief.

COMMANDER CHEYNE, who is in Montreal, says that he has not abandoned his proposed balloon expedition to the North Pole. Lieutenant Schwatka has offered to join him.

JOE HOLLIDAY denies that he is about to sell out and leave Portland. He says he is well satisfied with this city and its future, and that if Henry Villard or any one else wants to buy him out, it will take not less than \$3,000,000.

THE COMMISSIONER of the General Land Office has sent for delivery to the party legally entitled thereto, a patent for Rancho los Vallecitos de San Marinos, Lorenzo Soto, confirmee. This grant contains 8,777.29 acres, and is situated in San Diego county.

THE steel and iron workers of Pennsylvania intend to propose a plan whereby wages will be increased about 15%. A strike in this case is said to be not improbable.

A BOSTON dispatch says the entire subscription of the Mexican Central railway securities, under circular No. 4, amounted at the close to \$7,229,500, or \$1,197,000 more than asked for.

THE farmers in Virginia complain very much of petty larceny since the whipping-post was abolished.

GOVERNOR CLEVELAND has returned to the Assembly the bill reducing the rate for the New York elevated railroads, with a message giving his reasons therefor.

A SWEEPING decision against bucket shops has been delivered in the United States Court of New York State.

INTELLIGENCE from France states that the emente there is due to the fact that 60,000 persons are out of employment. A Times correspondent at Paris says that for the past few days many foreigners have kept away from that city on account of its unsettled condition. There are now at Rome many Americans who were about to start for Paris when the demonstration occurred.

AT OTTAWA, Sunday evening, a crowd of excited people collected in front of Professor Wiggins' residence and began to clamor for his appearance. As the doors and windows remained firmly closed, cries of "Fraud" and "Humbler" filled the air, and an attack upon his house was only averted by the opportune arrival of the police, who quelled the impending disturbance, and assured the mob that Wiggins was not at home.

ARCHAEOLOGICAL DISCOVERY IN ASIA MINOR. A discovery has been made lately by a Bavarian archaeologist, Herr Sester, at the point where the Euphrates bursts through the Taurus range. Here, in a wild, romantic district lying between Madatiah and Sanias, he found a line of megalithic monuments, averaging between 55 and 60 feet in height, and bearing inscriptions. They are in a remarkable state of preservation, and Herr Sester has no doubt that they formed a part of some great national sanctuary, dating back some 3,000 years or more. There was formerly at this place a necropolis of old Cominagene kings, so that it seems reasonable to attribute these colossal monuments to this ancient people, the hereditary foes of the Assyrians. Very little is known about them. The classical writers allude to them only in casual passages, and the arrow-headed inscriptions, although mentioning them very often, have hitherto yielded scanty information.

RICH rock has been struck at the Muck & Eckart mine, on Else creek, near Volcano. The shaft is down 150 feet, and a drift has been run on that lead north 100 feet. Here a four-foot ledge was found, the chimney being extensive. Ore is being hauled to the Gillick mill for crushing. Frank Keenan is foreman.—*Amador Sentinel*.

THE GOOD TIME COMING.—"The day is coming," says an exchange, "when a letter will go anywhere within the United States for one cent, a dispatch for ten, and a man for a cent a mile."

THE Santa Rita Copper & Iron Company, N. M., are working a large force of men on their mine and mill day and night, and are steadily shipping copper.

Successful Patent Solicitors

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

Look for Your Subscription Credit.

Subscribers on paying for this paper should look at the date of the printed labels on their papers, and if the same is not credited, in due time, up to the date paid to, be sure to write us without delay. If an agent or clerk receiving the money should inadvertently or intentionally omit credit, it is important to the subscriber and ourselves that we be informed of it IMMEDIATELY, that we may act accordingly. Subscribers will please notify us of all errors which they may notice of any kind on our mail list. Be sure to write us if the paper comes after you wish it discontinued.

Our Agents

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.
 G. W. McGraw—Santa Clara county.
 M. P. Owen—Santa Cruz county.
 J. W. A. Wright—Merced, Tulare and Kern counties.
 JARM C. Hoag—California.
 B. W. Crowl—Arizona Territory.
 L. Walker—San Joaquin county.
 N. H. Harp—Plumas county.
 A. C. Knox—Napa county.
 M. H. Joseph—Eureka, Nev.
 G. R. McDowell—Sonoma county.
 F. W. Stratton—Calaveras and El Dorado counties.
 I. M. Leiby—Los Angeles and San Bernardino Counties.

CHEAP ORE PULVERIZER.—There is for sale in this city, as will be seen by our advertising columns, a second-hand Rutherford Pulverizer, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

The Lemmon Herbarium.

This Herbarium has been removed from the Bake House to a permanent place at 1205 Franklin St., near Fourteenth St., Oakland, one square east of the Post Office, where plants of the Pacific Coast, including Arizona, may be determined on application, and instruction given in botany during the winter. Sets or single specimens of the rare and new ferns of the Pacific Coast for sale.

Agents Now Wanted.

Extra Inducements will be offered for a few active canvassers who will give their whole attention (for a while at least) to our business. Apply soon, or address this office, giving address, age, experience and reference.

DEWEY & CO., Publishers,

No. 252 Market St., S. F.

WATER TANKS.

Over 700 of our well-known Water Tanks put in service last year. These tanks are made by machinery, from the best of materials, and shipped to all parts of the country. Each piece numbered. No skill required in setting up.

WELLS, RUSSELL & CO.,
MECHANICS' MILL.
Cor. Mission & Fremont Sts., San Francisco.

\$3.85

This cut represents a No. 1 CALF SKIN SHOE, made in GAITER or LACE-up sizes, which we are manufacturing with a view to meeting the wants of a large class of people who must have the best shoe for the least money. It is guaranteed as to STYLE, FINISH and QUALITY, and will compare favorably with any \$5.00 shoe in the market. In order to introduce our goods, we will send FREE to any address for the LOW sum of \$3.85 a pair, thereby saving to the consumer the large profits of the jobber and retailer. TRY ONE PAIR AND BE CONVINCED.

F. H. WILSON, 232 West Baltimore St., Baltimore, Md.

Scientific Press Patent Agency.

Inventors on the Pacific Coast will find it greatly to their advantage to conslnt this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors ths expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homhastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinkley, Spiers & Hayes, 290 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

The Eureka Planer and Smoother.

The engraving on this page shows the "Eureka" surface planing machine, which has been improved and perfected as experience and practical use by experts have suggested, until, for general planing, requiring stiffness, durability, and speed in changing from one side to another, it is claimed to surpass all others at the price in the market. The machine weighs heavily, and it is really a big planer in a small way. Nothing will illustrate the solidity better than to say it will take a fine finishing cut, doing the very smoothest work; a few turns of the wheel lowers the bed, and a cut five eighths deep on hard wood can be taken. There are two sizes made, 18½ inches wide and 24½ inches wide, and they will work in either hard or soft wood.

The design for frame is best adapted for strength and strain, and is cast all in one piece. The bed being also cast in one piece, and the way it is dovetailed into the frame makes it a very stiff machine for all kinds of hard and soft lumber, and makes what mill men all look for, a cut free from ridges, and difficult to distinguish from that of the hand plane. The boxes for cylinder and rolls being cast on the machine makes very solid and rigid bearing, free from all vibration. The cylinder is of refined, wrought iron with twisted journals, and the bearings are long and lined with genuine babbit. A pressure bar goes on each side of the cylinder, thus insuring steadiness, even when planing short or thin stuff. The pressure bars are self-adjusting, always regulating themselves to the various lumber being planed. The changing of the machine to cut different thickness is quick and simple, the bed being raised and lowered by a single hand wheel. The feed rolls and cylinder being in stationary boxes, are always the same, and when the bed is raised or lowered, a glance at an index on side shows the thickness to be planed, and requires no further setting.

The four feed rolls are extra large, the front one being fluted, and are given extra pressure by double coil springs. The friction rolls in table are easily adjustable. The gearing is strong, and every device introduced to make a strong, reliable feed. It planes from one-sixteenth to six inches thick, and either eighteen inches or twenty four inches wide. A counter shaft is furnished if needed and can be either placed on the floor or under, as most convenient. The counter shaft has a flanged pulley on it to run to loose and tight on machine, thus stopping or starting the feed. The Berry & Place Machine Co., of this city, take particular pains in recommending this machine, which they guarantee to be a first-class one.

The copper mines of Arizona are at present returning larger profits upon the capital employed than is made in any other investment. The use of copper in the arts and the varied industries of the country is increasing. Most Arizona copper properties are far from railroad communication, and, notwithstanding the heavy expense of reduction, they are paying large dividends where energetically worked.

MINES now being opened by A. W. Callen, in Walnut Grove district, Arizona, have a healthy appearance. Everything is in readiness for the new mill.

CONCENTRATING works are to be erected on the Conway Castle property, near Galena, Idaho, Upper Wood river.

Mill Sites.

Mill sites are recognized by Sec. 2337 of the Revised Statutes, where the land is non-mineral, and is used by the owner of a vein or lode, and may be included in an application for a patent for such vein or lode, and can be patented with it, subject to the same preliminary requirements as to survey and notice as are applicable to veins or lodes; and the owner of a quartz mill or reduction works, not owning a mine or connection therewith, may also receive a patent for his mill site, as provided in the section.

There is this to remember, however: The

recorded in connection with lode claims by the proprietors thereof, whereby the land was legally appropriated; and, hence, that their prior location precluded location of the town site.

The Secretary of the Interior, on an appeal, reversed this decision of the Commissioner. The applications he held were by virtue of the provision under which there can be no mill site unless there is a lode or vein to which it may attach. The Secretary held to have the mill sites excluded from the entry of the town sites. Title must be first established to the mill sites. To do this the owners must show the non-mineral character of the ground. The Secretary thought this was not done, as not less than

cation was not made for mill site purposes, but to secure the same for town site purposes. This I think is quite apparent from the evidence. I think, as full opportunity was given to establish the title, there ought to be no further delay in this matter, and the patent for the town site ought to issue to the proper authorities, if their proceedings have been regular. It has been urged that if this town site is on mineral land, the entry ought to be canceled. That a town site may be located on mineral land cannot now be questioned. What are the rights of the lot-owners and mineral claimants within the boundaries of such town site, after entry, is a somewhat difficult question.

Taste and Odor of Minerals.

The chief of the so called chemical characters of minerals, or those which depend upon chemical composition, are taste, odor, solubility, fusibility and volatility.

Taste is a character of great importance in the case of some minerals. Thus, cyanosite, goslarite, melanterite, halite, or common salt, kalinite, nitre, nitratite, and a few other mineral substances, may be at once known by their taste, which is in each case very characteristic. The chief varieties of taste observed in mineral substances are as follows:

- Metallic—the taste of native metals.
- Metallic astringent—the taste of the vitriols.
- Sweetish astringent—the taste of alum.
- Saline—the taste of common salt.
- Alkaline—the taste of nitrate of soda.
- Cooling—the taste of nitre.
- Bitter—the taste of epsom salts.
- Sour—the taste of sulphuric acid.

The only minerals which have distinct taste are those which are soluble in water.

Odor is occasionally of importance. Thus many minerals containing alumina or magnesia give off a peculiar earthy smell when breathed upon; others which contain sulphur or arsenic when broken, rubbed or heated, yield a characteristic smell. The chief varieties of odor are the following:

- Alliaceous—the odor of garlic. It is observed on rubbing, heating or breaking ores containing arsenic.
- Horseradish odors—the odor of decaying horseradish. It is observable on heating or melting substances containing selenium.
- Sulphurous—the odor of burning sulphur, observable on heating, breaking, etc., many substances containing sulphur.
- Fetid—the odor of rotten eggs. It is given off by some varieties of quartz, barytes and limestone when broken or rubbed.
- Argillaceous—clayey. It is given off by serpentine and other substances containing magnesia.

INSTANTANEOUS FORMATION OF STEAM.—A firm in Paris, France, have patented an invention for the instantaneous formation of steam, which permits for its use at once in the cylinder of the engine. A pump sends the required quantity of liquid between two plate surfaces, which are heated, and between which there is only a capillary space. The liquid spreading in a thin layer evaporates at once, without going into the so-called spheroidal state, and this steam acts in the cylinder as fresh formed steam. The speed of the pump is regulated by the engine, the pump being connected with the shaft of the engine.

ALL is life and bustle in Walker district, Arizona. A great many houses are being built. The reduction works will be started in a very short time.

SILVER and copper mines were recently discovered north of Winslow, on the A. P. railroad, in formation similar to Silver Reef district, Utah.

THE EUREKA PLANING AND SMOOTHING MACHINE.

location of a mill site upon the public land of the United States does not operate as an appropriation thereof, so as to reserve it from town site location. The mill site men must show location, title and compliance with law as regards both lode and mill site, as required in a court of justice to establish such a claim.

Town sites may be located on mineral land. The question of relative legal rights of the town site and mineral claimant, as to occupation or possessory title to the surface, is not settled by any Land Office rules, but is left to courts of competent jurisdiction. It is the practice of the Interior Department of inserting in town site and mineral land patents mutual clauses of reservation.

Some time since certain mill site owners protested against certain town site locators in Colorado, to prevent an issuance of patent. The Commissioner of the General Land Office decided that the land in question was non-mineral; that the mill sites were duly located and re-

16 lode claims were marked on the map of the town.

The Secretary says: It is true that the statute is silent as to the location of mill sites; but it is not unreasonable to suppose such location must be made substantially as that of a mining claim. Such mill site location must be made by the owner or proprietor of a lode or a quartz mill or reduction works. The letter of the statute would seem to require that such mill site ought to be used in connection with such lode for mining or milling purposes, before a legal location can be made; it is not, however, necessary to determine that question in this case, for there is no proof that the protestants were the proprietors of any vein or lode. The protestants did not introduce location certificates of lodes, and, in connection with such lodes, the mill site locations; but there is no evidence that the lodes were taken in accordance with law; it does not appear that the locator complied with the local laws or the United States statutes concerning such location and the development of such lodes. Much has been said with regard to the good faith of the protestants as to the location of the mill sites, and it is charged that such lo-

CORRESPONDENCE.

Saving Flour Gold.

EDITORS PRESS:—In the PRESS issue of the 10th inst., in reply to Mr. F. W. Noble's letter, you give the best method of saving fine gold of which you "have any knowledge." I am a little interested in this subject, and with your permission, would like to say a few words in regard to it in your valuable paper.

Mr. Noble's statement that the gold on Snake river is free from iron rust may be correct, yet I do not believe that gold is found in gravel mines with a clean metallic surface. The surface of gold, when perfectly clean, has a strong affinity for mercury; but mercury, in its turn, must have a live, or bright surface; that is, be free from oxide before amalgamation can take place.

The silvered and mercurial plate, without doubt, has some advantages over the ordinary amalgamated copper plates, but, unfortunately, by a constant grinding, similar to that produced by a sand blast, these plates become coated with flour mercury, which has a great affinity for oxygen, thus retarding or utterly preventing amalgamation of fine gold. To prevent this, however, sodium amalgam has been used to great advantage. Again, these plates, when placed in the bottom of a sluice box having a great fall, will be found soon worn out, and retaining little or no gold. If the box, however, has but little fall, the surface of the plates will soon be covered with a layer of magnetic iron sand that prevents the gold from coming in contact with the mercury.

It is well known among miners that running water will carry with it fine particles of gold in suspension, and that muddy water holds a larger percentage of these particles; that they are usually flakey or flattened, rendering them buoyant; thus, being lighter than the sand, they are readily carried away with it. If an ounce of pulverized gold-leaf, for instance, and the same weight of finely pulverized marble are let fall from the same height, the gold will be found floating in the air, on account of its flakey nature, when the marble has all settled on the ground.

To this flattened or flakey condition, more than to any other thing, can be attributed the great loss of flour gold. The majority of placer mines are now, and always have been, richer in flour gold than in coarse gold, and how to save fine gold has always been a very important question.

Inventors have given much valuable time, and spent a considerable amount of money in the construction of gold-saving machines; however, little is known as to the results. I certainly side with you in regard to "toy machines," also that the best results cannot be obtained through carelessness and inexperience. I am thoroughly satisfied that a very high percentage of flour gold can be saved, as such has been precisely demonstrated at the placer mines of the Santa Rita mountains, Pima county, A. T., by an invention of a new principle, as I understand, in which specific gravity plays no part. The company making use of the invention are said to be thoroughly satisfied with its workings, saving besides coarse gold \$5 to 90 per cent. of the flour gold that otherwise would have been lost. I am not personally acquainted with any member of the company, but am told Mr. R. R. Richardson, of this city, is its president. If Mr. Noble, or any other miner who is interested in the saving of flour gold, will make inquiries of the above named gentlemen, perhaps they may obtain some valuable information, as the company do not make a secret of their success. F. A. OBERMATT, JR.

Tucson, Arizona, March 13, 1883.

A NEW ELECTRIC GENERATOR.—A new method of generating electricity has been discovered by Dr. Brand of La Rochelle. He has an electro-generative torch or candle which yields a current of electricity in the act of burning. It is thus described: It is prepared by making a paste of coal dust and molasses and molding it into a stick which serves as the inflammable wick of a candle. This rod is then covered with asbestos in a thin sheet, and dipped into fused nitrate of potash until a good thick coating of the nitrate adheres. The wick being ignited it burns away, and a current of electricity is drawn from the candle by wires inserted into the nitrate and the coaly wick. It is stated that Dr. Brand is experimenting to construct a fireplace so that the fuel burning in it will develop an electric current sufficient to ring electric bells or charge an accumulator and thus give light also. The discovery is as yet in its infancy, but scientific men in Europe think it will lead eventually to great results.

AN ASBESTOS BALLOON.—A fire-balloon has been made, in which the lower part is constructed of asbestos cloth, while the upper part is covered with a fire-proof solution. A spirit-lamp is used to supply the hot air for inflating it, and, being fire-proof, there is no risk as with ordinary hot-air balloons. The system is said to be specially valuable for war balloons, as a supply of spirit can be easily carried where it would be difficult to take the appliances for preparing gas.

Peabody.

A Live Company Makes a Live Camp.

From Mr. M. H. Smith, until recently a dweller in Tombstone, but now a business man in the new town at the Peabody mine, a reporter on the *Republican* learned the following facts:

The Peabody Company, under its new purchasers and the able management of Mr. Johnson, the general manager of the concern, have to a great extent torn down, overhauled, remodeled and rejuvenated the entire affairs at the mines and smelter. The smelter has been taken down and removed from its old site to within about 150 feet of the mouth of the mine. The water supply has been augmented and a steam pump has been put in which elevates the water to a height of 80 feet above the town, where an immense tank has been put up which will supply the mine, smelter and population. Another smelter has been ordered, and both of them will be in running order about the 5th of April. They are so arranged that the ore as hoisted from the mine is hauled on a tramway, upon which the car runs to the rock breaker and deposits the ore, which, after having passed through the crusher, falls into a bin near the smelters, from whence it goes into the furnace and comes out black copper.

The developments on the Dreadnaught mine are not favorable. A contract has been let to sink 100 feet on the Copper King, which is a promising location. The company have 103 men on the pay roll, among whom is not one Mexican or Chinaman. They pay four dollars per day for top and bottom men, and do not propose to debase their countrymen by bringing them into competition with cheap labor of any nationality.

The owners of the property are Lake Superior copper men with immense capital. Mr. Johnson, the general manager, has had 20 years' experience in the mines of Lake Superior, and knows just what he is about. He is also a heavy owner in the company. The people there all speak in the highest terms of the man. To show what sort of a man he is, a brief recital of the foundation of the new town is necessary. When the smelter was removed from its old site, three miles away from the mine, that event destroyed the prospects of Russellville, the old town; so people began to cast about them for a new location. They hit upon a place one fourth of a mile from the Peabody mine. The lay of the ground was most eligible for building purposes, but the surface belonged to mining locations. To settle all questions, the owners deeded the surface to Mr. Johnson in trust for actual settlers, and Mr. J. G. Parke, late of Tombstone, the company's engineer, went to work and surveyed the place off into blocks, lots and streets.

The streets run with the cardinal points of the compass, and are 80 feet wide. The lots are 30x150 feet, and each block has an alleyway through the center 20 feet wide. When 300 bona fide settlers have located and built upon lots which they are allowed to locate, a petition will be made to the probate judge to the property, and they will be assessed pro rata to pay the cost of survey, records, deeds, etc., when the remainder will belong to the town site company and will be sold by them. Thus it will be seen that there will be no contest over the matter with any one, and every person will get a good title to their property for a nominal sum. Mr. Parke is deserving of a portion of the credit for this happy solution of the town site question along with Mr. Johnson.

The town has now a population of 300 people and building and improvements are the order of the day. There are seven business houses that now pay license, and this number will be greatly added to as men get up houses and the necessary improvements. Mr. Smith has built an elegant saloon, which has just been opened, and Andy Meham has another nearly ready for occupancy. The old hotel at Russellville will be moved down to the new town in a short time, which, with the restaurants and lodging houses now in operation, will accommodate the residents and traveling public.

Last week there was a large party of eastern capitalists at the mine, among whom were several owners in the Peabody. They were delighted with the showing of wealth in the mines. It is predicted that the new order of things will build up one of the greatest copper centers in Arizona and will add a million or more to the taxable property of Cochise county. The Williams brothers will now have to look to the laurels of Copper Queen for they have a rival in the field worthy of the name.

MACHINERY STEEL.—The *American Machinist* says that machinery steel is not easily welded sometimes, and the following plan, which was hit upon after experiment, proved successful. A good heat was taken, the two bars placed together and lightly tapped to stick them fast. The weld was then put in the fire again, a good heat given, and the scarf thoroughly hammered. This proved a success every time. No borax was used.

A NEW STORM INDICATOR.—*Les Mondes* reports that M. Dufourcet has, in the exposed court of his house, two bars of iron planted in the earth, to each of which is fixed a conductor of coated wire, terminating in a telephonic receiver. He consults the apparatus twice or thrice every day, and it never fails through its indications of earth currents to give notice of the approach of a storm 12 to 15 hours before it actually arrives.

The Coronado Mines.

The Clifton *Clarion* (Arizona) says: At the time of the purchase by the Scotch syndicate of the mining properties of the Lesinsky Bros., the Coronado group, being the farthest away, had the least development done on them, although, in the opinion of practical miners, there were no mines in the district which gave promise of producing more bullion when developed, an opinion which was coincided in by the experts sent out from Scotland and the East to examine the various properties and report upon them. After the sale was completed and the transfer made, the extension of the narrow-gauge railroad was pushed along rapidly, and by the last of March or the fore part of April at the farthest, the cars will be running to these properties. The Coronado mines proper consist of six locations, running consecutively from east to west on Coronado mountain. Beginning at the eastern slope of the hill, they are named as follows: Matilda, Copper Crown, Crown Reef, Coronado, Horseshoe, and Boulder, 9,000 feet long in length of surface ground, besides other properties. From the Matilda down to the Boulder, a distance of one and a half miles, there is a vertical difference in depth of 1,000 feet, and over this entire distance the croppings are very plain. The ore body is a well-defined contact vein, with syenite on the north side and quartzite on the south. The principal work has been done on the Matilda and Copper Crown on the eastern slope, and on the Horseshoe on the western slope, running down toward Eagle river. The upper incline railway passes through the hill by a tunnel cut on the ore vein. "This tunnel, when completed, will be 1,200 feet in length. It is now in just about half of the distance. This tunnel will afford facilities for getting out the ore from the Horseshoe and other claims on the extreme west, which will be connected with the main track by means of incline railways, and at the same time stopping can be done at any point along its entire length with but slight interruption to the transfer of cars. This tunnel enters the hill at a point 306 feet below the summit. The present workings on the eastern slope consist of three levels, the main, or railroad tunnel, one 80 feet above it, and one 100 feet below, numbered from above one, two and three. These levels are connected by winzes, and the ground is ready to stop whenever the ore is needed. The vein being vertical, work will be continued by winzes and levels. The Horseshoe shaft, on the western slope, has been sunk to a depth of 165 feet. At a depth of 100 feet, crosscuts were run north and south, cutting the north wall in 25 feet, and the south wall in 43 feet. In the north crosscut, low-grade ore was found the whole distance; in the south one or two veins were cut, four and six feet in width. The average width of the vein in the Coronado mines is four feet, and the assays average 14 per cent. copper, the assay statement being the result of hundreds of tests. This group, as well as the other mines of the Arizona Copper Co., are under the charge of W. S. Smith, C. E., and directly in charge of Mr. J. C. Schmitt, who, as foreman, assumes the direction of the workings underground.

Low Grade Ores.

Cheap Method of Working Them.

The *White Pine News* has the following relative to working low grade ores: "Supt. Foulke has for several weeks been experimenting with two of Frue's concentrators at the Star mill. We took a walk up to the mill a day or two ago, and found these machines running smoothly and in perfect order. Five stamps are used to crush the pulp that feeds them, and, of course, the poorest grade of ore is selected for these stamps. By this method of concentration, 25-dollar ore is worked to a profit, 75 per cent. being realized from its assay value. No. 30 screens were at first employed on the concentrators, but a gradual grading down showed improved results, until now a No. 16 is in use and Mr. Foulke thinks a No. 12 or 14 will be an improvement even on that. The result of the experiments so far has been entirely satisfactory, and Mr. Foulke believes that this process will prove the salvation of his company, and cannot fail to work wonders for all districts whose mines carry large quantities of low grade ore that cannot be worked at a profit under the old milling system. Another very important item resulting from the concentrators is that the grade of the bullion produced is much finer; the Star bars have improved in grade from 470 to over 600 since the new system has been in operation. It also saves much labor in handling and sorting ore, the services of seven men in this capacity having already been dispensed with at the Star.

"If this system of concentration can successfully be applied to all the ores of this district—and there appears no reason why it cannot—we may confidently look for three or four companies operating here in the not distant future. There are thousands of tons of low grade ore here that only await some cheap process for profitable reduction. We shall watch with interest the Star Company's progress with Frue's concentrators, and from time to time note the result. If it proves as successful as its owners predict, it will surely cause a revolution in the industry of hundreds of now almost deserted camps in Nevada, and place those that are struggling against heavy odds for existence on the high road to prosperity."

Santa Fe District.

A Promising Region for Prospectors.

A correspondent of the *Virginia Enterprise* writing from Luning, says: The Occidental copper mine, situated in Santa Fe district, three and one half miles east of Luning, on the Carson and Colorado railroad, is, we believe, the coming copper bonanza of Nevada. It is a blind ledge, but is found by exploration to be from 150 to 200 feet in width, and is already opened in nine different places, a distance of 1,000 feet along its course. Its ores are excellent, containing almost all kinds and characters of copper. Red and black oxides, carbonates, peacock, native bluestone and native coppers, are found in this mammoth ledge, and the ledge shows wonderful strength as depth is attained.

We do not hesitate to say that we believe the Occidental copper mine to be one of the most valuable and promising copper mines in the State. There are already thousands of ore, of good quality in sight, and it contains iron sufficient for smelting.

The location is most favorable, as an excellent site for a smelter can be had, with an abundance of water in sinking 60 feet, within a mile and a half of the mine, all the way down grade. Already the company has completed a good wagon road from Luning to the mine, which is of great value to its owners, as a wagon can drive directly to the ore dumps, and no packing with animals is required.

This mine was lately discovered by its present owners, the Chrisman brothers, formerly of Dayton, who have for the past nine months kept up a continuous search with untiring zeal for precious metals in this locality, and who are now handsomely rewarded.

The company are sinking a shaft on the ledge, which is down several feet, all the way in gold smelting ore. In the shaft has been encountered a large deposit of very rich ore. Native copper has been found all through it. This is being prospected by a drift from the shaft. Samples of ore taken from this rich find in the shaft goes way up to 50%, 60% and 70%.

It is simply wonderful the amount of copper in this mine. Dig almost any place you may, and by removing but a few inches of the surface good copper is found. It seems to be a whole hill of copper. The formation is granite and black lime.

There are also several other good mines joining and lying near the Occidental. Among them are the Hawkeye, Mocking Bird, Cabin and Nevada, all showing very fine specimens of copper. As high as 36 per cent has been found almost on the surface. But little work has been done on any of these, but with proper exploration, I believe they will prove good properties. There are many other good mines in this district. To the north lies the Calamity, Illinois, Sweet Vengeance, and many more, all good and valuable mines. The Illinois and Sweet Vengeance, I understand, are already bonded for quite a sum to eastern capitalists. To the east, lies the Tiptop, Copper King, and many other valuable mines.

What this district most needs is smelters, and I understand some New York capitalists are here for the purpose of erecting a smelter in this vicinity. This country is only in its infancy as regards mining and prospecting. New and valuable discoveries are being made almost daily, and with the return of spring there will be a grand rush for this country by capitalists and prospectors, and no doubt many new and valuable discoveries will be made, as copper is attracting the attention of the mining world more and more every year. This is sending many in search of this valuable and profitable metal.

COPPER MINING.—The Omega Copper Mining Co., of Philadelphia, have recently contracted with the Pacific Iron Works, Rankin, Brayton & Co., San Francisco, for one of their famous water jacket smelters to be erected at once upon their mine in the Helvetia district, near Tucson, Arizona. The Omega is a well developed mine, and gives promise of being one of the most productive and valuable mines in that Territory. We feel assured that this company have made no mistake in the selection of their reduction works. The Pacific water jacket for both copper and galena ores, have been a most signal success in all parts of the country and with all classes of ores, and we know of no other that can be considered as anything more than an experiment. In the interest of mining, it may be said that no company can afford to purchase any machinery but that of established character and reputation. The Chicago branch of the Pacific Iron Works, recently established, has, we understand, a large amount of iron work in hand destined to various localities. The establishment of these works is a much needed enterprise, and a matter of genuine satisfaction to Eastern mining operators, who are thus enabled to avail themselves on this side of the continent of the practical experience and skill of this well-known firm, and we predict for them a large and constantly increasing trade. All parties contemplating the erection of any kind of mining, milling or smelting machinery would doubtless consult their interest by communicating with them. *Philadelphia Mining Journal*.

A REPORT comes from Silver Canyon, says the *Cherry Creek News*, that a very important strike has been made in that camp. Much excitement is said to have prevailed over the affair, and many new claims were located.

MECHANICAL PROGRESS.

The Relative Economy of Solid and Gaseous Fuel.

The London *Journal of Gas Lighting* states that an article in a recent number of *Le Gaz Belge* deals with the question of the economy of gaseous as compared with solid combustible for domestic or industrial purposes. The writer commences by remarking that when combustion takes place, the quantity of oxygen required by the carbon does not by any means correspond with that required by the hydrogen; and as these elements are not generally separated, a certain quantity of one or the other must be burnt to waste. The carbon can only combine with the quantity of oxygen necessary to form carbonic acid, and the hydrogen takes up only that which will produce aqueous vapor. The former of these elements therefore always absorbs more oxygen than the latter, supposing that there is sufficient to ensure complete combination.

When solid fuel is employed, it is not only necessary to provide the supply of oxygen required for combustion, but also to convey into the furnace sufficient air to drive off the products of that combustion, by ensuring the contact of the oxygen with the whole surface of the combustible material. In practice it is found that nearly twice the quantity of air theoretically required has to be provided; and this, of course, doubles the volume of the gases that have to be heated. It may thus be assumed that half the air admitted into a furnace does not serve for combustion; and this excess of air naturally carries off a considerable quantity of heat. The loss, however, is a necessity; for, if less air were supplied there would be a possibility of combustion being incomplete, and the evil would become greater. In fact, the carbon passing into the condition of carbonic acid (the result of the most complete combustion) develops 7,200 heat units; while with a less perfect transformation it furnishes carbonic oxide, giving only 1,400 heat units. When gaseous combustibles are utilized, these losses may be prevented; since very nearly the determined quantity of oxygen may be supplied, and this be caused to mix more closely with the combustible elements, without necessitating the expenditure, on the part of the mixture, of an amount of energy comparable with that required by the solid combustibles.

The commercial value of the two kinds of combustibles may be approximately stated as follows: Coals have, according to their quality, a standard of from 4,500 to 7,500—say an average of 6,000—heat units. From this number must be deducted 500 heat units lost in effecting combustion. There remain, therefore, 5,500 heat units. Now, the absolute available heat of furnaces employed for industrial purposes does not exceed 40% of their theoretic heating capacity, and, therefore, the effective calorific power is reduced to about 2,000 calories. The cost of furnace coal of average quality ranges from 6 to 8 frs. per 1,000 kilos—say 0.8c. per kilogramme (2.2 pounds). The 2,000 calories heating power, therefore, cost 0.8c. If coal gas is taken as the element of comparison, its yield in heat being 12,000 units of the net cost of 7c., the ratio becomes 1:4 for coal and gas respectively. This, however, is exclusive of the cost of labor, maintenance of appliances, transport of fuel, etc., all of which would double the net cost of the solid combustible material. So that the proportion really becomes 2 for coal and 1.4 for gas. But the solid combustible furnishes only 2,000 calories, while, if it is transformed into lighting gas, it would furnish 3,000 calories. The final ratio of net cost, therefore, becomes 3 for coal against 1.4 for gas; in other words, the employment of illuminating gas as a combustible is attended with about twice the economy that results from the use of ordinary coal.

PAPER RAILS AND CAR WHEELS.—The *Northwestern Lumberman* is quite skeptical in regard to the introduction of paper as a substitute for iron in the manufacture of rails. That paper thinks the accomplishment of the idea is extremely doubtful. In the first place, it claims that there is literally no such thing as a paper car wheel. The office of paper is merely to furnish filling, the plates and bands being of iron. If the friction and pressure were applied to paper direct, it could never stand a fraction of the grief to be encountered. It is hardly more probable that a paper rail could do any more. If it is an iron or steel rail on the half shell, stuffed with *papier mache*, it may be different; but a chunk of paper that will turn the point of a spike must be in somebody's mind.

A SAFETY valve should be large enough to discharge all the steam the boiler is capable of making. The following rule is that enforced by the United States Government in fixing the area of safety valves for the boilers of ocean and river vessels, when the ordinary lever and weight safety valve is employed. When the common safety valve is employed, it shall have an area of not less than one square inch for each two feet of grate surface. The following rule has been prepared by Prof. Thurston: Multiply the pounds of coal burned per hour by 4, and divide this product by the steam pressure, to which the constant number 10 is added,

Can Iron be Burned in Melting?

The following answer to the above question is given in a contemporary: The writer, a few days since, met a foundryman who was in constant fear of getting his iron too hot. He claimed he was melting his iron just as hot as possible without burning—that if he melted it hotter it would surely be burned. This is one of those strange delusions that sometimes trouble the minds of otherwise sensible people. Now, this man, and any others who may entertain the same views, what basis have they for their opinions? A few years ago the question arose in a foundry, and might fairly be asked: "Can iron be burned in melting in a cupola?" To settle this, test bars were cast at one heat, just coke enough being used, as some would claim, not to burn the iron. The next day test bars were cast of exactly the same dimensions and from the same mixture of iron, enough coal being used to melt the iron so hot that it was yellow, a titful flame arising from it when in a dry ladle. The bars from the two heats were afterwards tested in a testing machine, when it was found that the bars cast from the hot iron were more than nine per cent. stronger than those cast from the iron which was said to be just as hot as could be made without being burned. Now for the reason: It is generally the case that in putting up iron for ordinary machinery castings, two, three, four or perhaps five kinds and qualities of iron are used. It is of the utmost importance, especially for such castings as cylinders, steam-cylinders, cylinder heads, and finished work generally, that the castings be made homogeneous.

When iron melts in a cupola, it is essentially different from the melting of ice in water. The iron gets soft till it falls in pieces from the pig, and these pieces into still smaller pieces, and the liquid condition is assumed, which means the separation of the molecules that were united to form the solid iron. Now, the hotter the iron gets, the more complete the separation of the molecules of each particular brand, and the more readily they will mix when they come together in the bottom of the cupola. As soon as the disintegrated pig gets hot enough to liquefy, it does not stop long in one place, but descends to the bottom of the cupola, and any additional heat it receives must be imparted in the transit from the melting point to the bottom. It is not claimed that too much fuel cannot be used in a cupola. On the contrary, a surplus over and above that required to melt hot liquid iron may be used, which means an extravagant use of fuel. It has no effect on the quality of the melted iron, but it has the effect to make the cupola melt slow, and enough fuel may be put in a cupola to absolutely prevent melting. In stove-plate foundries iron is generally melted much hotter than in machinery foundries, and the writer has always observed that in foundries where the iron is melted hot, the average of the work is much better, and the percentage of poor castings is much less, than where so much caution is exercised to prevent burning the iron in melting.

Steam Boilers.

The strength of iron in boilers is not much affected by the working temperatures up to considerably over 400° F., nor by the low temperature down to the freezing point. But, when the temperature of the plates, through the absence of water or from any other cause, rises much above 500°, then a change commences. Above 750° the tenacity diminishes very rapidly, and when the plates become red-hot, they have lost fully half their usual strength.

As riveted joints destroy the elastic homogeneity of the boiler, the waves of expansion, contraction and vibration are arrested there by the greater rigidity of the riveted double-thickness of metal, which tends to localize the fatigue sustained by the iron near these points, and it also appears to increase the susceptibility to corrosive action, since the furrows generally take the line of that fatigue, and are often deeper than the spots on the plates.

Flues of 16 inches diameter must not be less than one quarter inch thick, other flues in proportion, and not less than three inches from the shell.

A 42-inch boiler, single riveted of one fourth inch iron, will safely bear a working pressure of 110 pounds to the square inch, and must be tested to a hydrostatic pressure of 165 pounds to the square inch.

The experiments made by Fairbairn in 1838 have served, up to the present time, as the basis of calculating the strength of riveted joints. According to these experiments, the strength of a double-riveted joint is 70 per cent. of the strength of the plate; and of a single-riveted joint 56 per cent. Of these experiments it is necessary to remark:

1st. That the results are only for the case in which the rivet holes diminish the section of the plate 30 per cent., while for the most part in practice, and particularly for the single-riveted joint, that loss is very much greater.

2d. That the experiments were made on plates of only 0.224 inch thickness.

3d. That the experiments gave 46, and not 56 per cent., for the strength of the single-riveted joints.

THE parties who purchased the Centennial building, in Philadelphia, for \$97,000 have already realized \$405,000 from the iron in it, and have sold the debris for \$100,000.—*Ex.*

SCIENTIFIC PROGRESS.

Electric Excitement.

We recently made some allusion in this column to a device introduced by Mr. F. W. Whiting, of Boston, by which the belts, machinery and surrounding air in a factory are relieved of the electricity generated by the moving machinery. It is well known that the presence of electricity so generated in a cotton or woolen factory is often the cause of much annoyance, sometimes affecting the fibers of wool and cotton to such an extent as to seriously impair the character of the goods in process of manufacture.

It is well known that wires have been attached to belts and grounded, by way of water pipes, for many years, and the electricity thus carried off; but the novelty of Mr. Whiting's method consists in two points. First, in attaching to the wire, by which the electricity developed on the belt is conveyed to the water pipe, a set of round balls in place of points. Electricity, being a form of energy developed upon surfaces, is more easily gathered upon the balls than upon the points. But the completion of this method requires that the machines themselves shall also be "grounded," by a wire attached to some part of the machine, and conducted to the ground by wire to a water pipe, or in some other method. This puts each machine into an electric circuit, one pole being at the belt, the other at the machine. In this way, the current of electricity is carried away from the stock, instead of through it, into the atmosphere, each machine or set of machinery forming part of an electric circuit grounded at both poles.

It often happens that the trouble on a speeder, for instance, is often caused by the electricity generated by a belt a long distance off, and conveyed by the shafting through the room. In this way the entire space may be filled with electricity generated at one end of a room.

This double arrangement of Mr. Whiting's is attracting the attention of cotton spinners and wool carders, and has already been applied with marked success in one of the largest New England mills. Thus far the application has been made wholly on cotton work, but attention is now being given by the gentleman who has devised this attachment, to the electricity on the rub rolls of a finisher card. Unlike most improvements of this kind, it will not be patented, as it is devised for the benefit of the members of the company with which Mr. Whiting is connected, and freely given to the world by the inventor.

THE COLOR OF PURE WATER.—Simple as such a thing may appear to be, it has nevertheless been found very difficult to determine the color of pure water, or at least scientists differ quite widely in their estimates. A special effort has recently been made by Herr Victor Meyer to settle this question, and he has found that it is a shade between blue and green. Taking two glass tubes 40 millimeters in diameter and about 1.5 meters in length, he connected them by means of rubber tubing, forming a tube about 7½ meters long. Both ends of this tube are fixed in glass plates and fitted with metal sockets, which are provided with brass nozzles for filling the tube. All being arranged, the tube is placed in a perfectly horizontal position and covered with a black cloth. Upon looking through the empty tube, the field of vision appears colorless, as the cloth and the metal sockets prevent the glass from exerting any influence. As soon, however, as the tube is filled with distilled water, an intense bluish green color is observed.

A TRIBUTE TO DR. DRAPER.—Mr. Richard A. Proctor pays, in *Knowledge*, the following tribute to Dr. Henry Draper: "We hear with extreme regret of the death of Dr. Henry Draper, Professor of Physiology at the University of New York. It has followed very soon after the death of his father. In Dr. Henry Draper science loses an honest and zealous worker, one who has devoted time without promise of reward to his scientific work; nay, has expended more money in his free gift of labor to science than some advocates of the Endowment of Research have begged for. The discovery that oxygen, and probably nitrogen, exists in the atmosphere of the sun is due to Dr. Draper, and would of itself suffice to keep his memory green. Scarcely less important, however, was his success in photographing the spectra of stars and planets, of Wells's comet, and the great Orion nebula. The zeal and devotion with which he discussed the photographic methods available for observing the transit of Venus in 1874 were fully recognized by his fellow workers in science, and even, wonderful to relate, by the government."

THE FORMATION OF CRATERS IN THE MOON.—At a late meeting of the Academy of Sciences at New York, experimental researches on the formation of the peculiar craters in the moon were communicated by M. Bergeron. He sends hot air through a brass tube into a melted but gradually cooling mass of Wood's alloy. The huddling of the air forms a circular space, first like a circus ring and then like a crater. Soon, however, the mass becomes pasty, and forms a cone in the middle. Some slightly different effects were had with other alloys, such as a more broken up appearance on the side of the cone. An interruption of the current gave rise to the formation of two concentric craters.

A New Sweet Compound.

C. Fahlberg, in a paper read before the Franklin Institute, Jan. 17th, furnishes some interesting particulars in relation to his discovery of a certain sweet compound in the hydrocarbon of the coal tar group. He describes the sweetness as being very intense. As soon as he made the discovery he proceeded at once to determine whether it was poisonous to take it in larger quantities or not. At first a cat and then a dog were subjected to experiment, but they remaining alive and apparently not in the slightest degree affected by it, the discoverer decided to take several grammes of it himself. The result was not the slightest inconvenience experienced from it. A chemical test of the urine, made the next morning, showed that almost the entire quantity taken could be thus recovered.

The compound obtained, and which contained the sweet principle forms salts with any carbonate of the alkalis, alkaline, earths or metals, and all of which taste sweet. It is, however, not an acid, but belongs to a class of bodies to which the name "Sulphines" has been given; the compound in question being benzole sulphide. It is very readily soluble in alcohol, more so than in cold water, in which it only dissolves readily when it is hot. The discoverer says:—"I am making the attempt now to prepare it in larger quantities and by cheaper methods, and have no doubt that it will find extensive use in medicine and for technical purposes. One experiment made was to sweeten glucose, which, as you all know, tastes only faintly sweet, and the result was a complete success. As soon as I shall have found the method by which to prepare it on a manufacturing scale I shall come before you again, and as I trust and hope, with larger samples than now, ready to give answer to all questions in regard to its price, application, etc."

HEAT AND MAGNETISM.—L. Pilleux has lately called attention to the heating of iron during its magnetization. The fact had previously been observed by D. Tommasi in some researches, which are not yet published, upon the comparative study of the chemical properties of ordinary iron and of magnetized iron. In order to obtain a constant magnetic intensity he employed an electromagnet of single branch in place of an ordinary magnet. When the current, even if it was produced by a weak battery, had traversed the coil for some hours, the magnetized bar became perceptibly warm. He at first attributed the heating of the iron to the heating of the coil; but he was greatly astonished one day when he had removed the bar in order to clean it and had forgotten to interrupt the current, to find that the coil was not heated at all.—*Les Mondes*.

LIGHT OF COMETS.—According to Huggins, comets emit a characteristic light which indicates, by spectral analysis, the presence of carbon, hydrogen and nitrogen, elements which are shown by the spectra of acetylene and cyanhydric acid. Berthelot thinks that these results point to an electric origin of the light. He has shown that acetylene is formed immediately and necessarily whenever carbon and hydrogen come under the influence of the electric arc. When nitrogen is added to acetylene the electric influence produces cyanhydric acid. It seems scarcely possible to conceive of a continuous combustion in cometary matter, but an electric illumination may be easily understood.

THE ACTION OF CEMENT ON LEAD PIPE.—Herr Bamberger reports the following *apropos* of his examination of a piece of lead pipe which had rested for years in a layer of Portland cement: It was coated with a red layer 1 to 3 mm. in thickness, resembling litharge in appearance, with a composition PbO 85, Pb 13, other matters 2. This film was carefully removed. Its specific gravity was between 8.002 and 9.670, the difference being due to the presence of adhering metallic particles of lead and lead carbonate. This coating appears to have been produced by the action of the oxygen of the air, in conjunction with that of the lime contained in the mortar, from which it would appear that lead in contact with lime, and with access of air and moisture, is actively corroded; a hint which builders, plumbers, and others, would do well to bear in mind.

THE HIGHEST MOUNTAIN PEAK.—For many years Mount Everest, in Nepal, has been considered the highest mountain in the world, reaching the respectable height of 29,002 feet. Dhawalagiri and Kuchinjunga, in the same range, with about 28,000 feet each, shared the honor between them until Major Everest, of the Bengal Engineers, discovered their big brother. Before they were measured, Humboldt thought some points in the South American Andes reached the highest altitude on our globe. But quite recently Capt. J. A. Lawson has discovered in the little-known island of New Guinea, a peak that is still higher, which he has appropriately called Mount Hercules, and fixes its elevation at 32,786 feet above the level of the sea.

BLEACHING BY ELECTRICITY.—Dobbie and Hutcheson have experimented upon bleaching by the aid of electrolysis. For this purpose the stuff is dipped into sea water and then passed through hot rolls which are connected with the poles of a galvanic battery. In order to decompose the hypochloride which is thus formed, the cloth is drawn through diluted acid and fully bleached.—*Dingler's Journal*.

Navajo, March 19th, \$18,150; Yellow Jacket, 19th, \$7,600; Final Con., 6th to 14th, inclusive, \$11,645.91; Martin White, 14th, \$2,237.08; 16th, \$2,180.90; Northern Belle, 15th, \$6,308.10; 12th, \$8,036.49; Yellow Jacket, 17th, \$7,558.49; Bodie, 19th, \$7,035; Christy, 15th, \$4,306; Standard, 12th, \$19,028.65; Contention Con., 10th, \$20,415.33; Bodie Tunnel, 19th, \$2,518; Park City, 15th, \$3,720; Hanauer, 15th, \$4,264; Mammoth, 15th, \$3,063; Park City, 16th, \$1,500; Mammoth, 16th, \$2,955; Horn Silver, 16th, \$6,000; Frisco, 16th, \$4,139; Ontario, 17th, \$6,218; Horn Silver, 17th, \$9,000; Ontario, 17th, \$9,843; Hanauer, 17th, \$2,350; Stormont, 17th, \$3,300; Germania, 17th, \$2,260; Alice, 17th, \$6,266; Horn Silver, 18th, \$12,060; Ontario, 18th, \$6,187; Sullivanville, 18th, \$6,053.

Mining Share Market.

Business at the stock board has been very dull for the past week, and prices have been low. Yellow Jacket has been up and then down again. The cause of Yellow Jacket's upward flight and subsequent retrograde movement is a mystery. From the mine nothing of special change has been received. There are those, however, who believe that something important has occurred in the ore vein on the upper levels, which is being kept secret for the present by parties who are desirous of buying. The change in the Albion Con. management took place as was anticipated—Mr. Fish displacing Mr. L. L. Robinson as President. The latter received \$500 a month as President; the former receives \$50. The new Board of Trustees, it will be seen, have commenced to practice economy, and pay nominal salaries only.

WHILE in San Bernardino, says the *Semi-Tropic*, we were shown some very rich specimens of gold and silver bearing rock, that came from the vicinity of Twenty-nine Palms, by Thomas Lyons, of the European Hotel.

MINING SHAREHOLDERS' DIRECTORY.

Pyramid, New Mexico.

EDITORS PRESS:—This camp is located some nine miles southerly from Lordsburg, on the Southern Pacific R. R., and embraces many mines of much promise. Among which may be named the Last Chance, Viola, Miser's Chest, etc.

The event of the times in this part of the country is the starting up of the Pyramid Co.'s mill, which has been in course of construction for the past six months. This company is composed of eastern capitalists mostly from Rochester and Auburn, N. Y., who purchased about a year ago from Col. Green, the Viola mine. After a few months further work upon the property the development was of so favorable a character that the company decided at once upon the erection of a mill and contracted with the Pacific Iron Works, Rankin, Brayton & Co., of San Francisco, for a 20-stamp furnace mill, embracing all their latest improvements.

The contract for construction was given to J. W. Pender, a mill builder of large experience, under whose immediate supervision the work has been constructed. The mill is a splendid specimen of work, no expense having been spared either in material or construction, and it is conceded by all our experienced miners to be the most perfect and complete in all its appointments of any now running in Arizona or New Mexico.

The machinery, like all that turned out at these works, is of the latest and most improved construction, designed especially for the thorough and economical treatment of base ores, and consists principally of a 100 H. P. Wheelock automatic cut-off engine, and boilers of like capacity; a 20-stamp dry crushing battery, furnished with self-feeders, elevators and conveyors; a 60-inch Howell chloridizing furnace, with Pacific revolving dryer; 10 five-foot combination pans, 5 eight-foot settlers, retorts, melting furnace, quicksilver elevators, crusher, grizzlies, etc., including all other appurtenances of a first-class modern mill.

So far as it has been run the capacity is considered much beyond that of other mills on this class of ores, while the ore is being worked up to 96 per cent. of its assay value.

This is considered by the most experienced mill men the best results yet obtained on ore of so base a character, and is evidence of the superiority of the work and thoroughness of construction. The building of this mill has given a great impetus to mining in this vicinity, and large shipments may be looked for from this camp within the next 12 months. H. A. W.

Pyramid, New Mexico, March 19th.

Meetings and Elections.

ALBION CON. M. Co.—March 17th. Directors—S. Heydenfeldt, Charles H. Fish, Henry T. Scott, P. A. Wagner, Julius Jacobs, A. J. Ralston and Samuel Hart. Charles W. Fish was elected President, and A. W. Havens, Secretary.

CHOLLAR M. Co.—March 21st. Directors—A. K. P. Harmon (President), C. L. Weller (Vice-President), Wm. Norris, J. D. Fry, J. H. Robinson, W. E. Dean (Secretary), Isaac L. Requa (Superintendent).

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANES, State Mineralogist.]

CATALOGUE.	DESCRIPTION.
4726.	Basaltic Column—Giant's Causeway, Antrim county, Ireland. J. Z. Davis.
4727.	Mountain Leather—A variety of Amphibole, found 18 feet below the surface, near Pine Grove, Amador county, California. (See 4726.) J. Z. Davis.
4728.	Arrow Heads of Yellow Jasper—Tehachan mts. near Tammam Parish, Louisiana. J. Z. Davis.
4729.	Grotesque Figure in Baked Clay—Made by the Indians living on the banks of the Gila river, Arizona. J. Z. Davis.
4730.	Cardium Corbis—post tertiary Fossil, Sequoia, Santa Cruz county, California. J. Z. Davis.
4731.	Co. cretions of Limonite—Found near Pine Grove, Amador county, California. (See 4726.) by their external appearance they are coprolites (No. 433), which are the same, were so labeled. J. Cooke.
4732.	White Marble—Glacier Bay, Alaska. Frank Taghlin.
4733.	Indian Implements of Baked Clay—With human bones found in an Indian mound five miles from the Dalles, Oregon. D. Morgan White.
4734.	Silver Ore—Sunrise mine, Taylor district, White Pine county, Nevada. J. R. Ryan.
4735.	Silver Ore—Contains native silver in Calc Spar and Barite—San Gabriel Canyon mines, San Bernardino county, California. Charles M. Tyler.
4736.	Rich Silver Ore—King mine, Calico district, San Bernardino county, California. Charles M. Tyler.
4737.	Rich Silver Ore—The Eva mine, Calico district, San Bernardino county, California. Charles M. Tyler.
4738.	Silver Ore—Oriental group of mines, Calico district, San Bernardino county, California. Charles M. Tyler.
4739.	Silver Ore—Burning Mesquite mine, Calico district, San Bernardino county, California. Charles M. Tyler.
4740.	Silver Ore—Occidental mine, Calico district, San Bernardino county, California. Charles M. Tyler.
4741.	Silver Scales from a cave near the Silver King mine, Pine county, Arizona. J. Holmes.
4742.	Fossil Leaves—Coal mines, Carbon Hill, Washington Territory. D. Morgan White.
4743.	Silver Ore—Run over mine, Calico district, San Bernardino county, California. W. H. Raymond.
4744.	Quartz with Gold—Electrum—Bodie mine, Mono county, California; very rich in gold, examine carefully. J. M. Claassen.
4745.	Silver Ore—Bonanza King mine, Slate range, 1100 feet above California. J. M. Claassen.
4746.	Azurite, Malachite and Cuprite—Kerrick mine, Banton, B. d. Springs, Mono county, California. J. M. Claassen.
4747.	Chromite—100 lbs. mass of Chromite, Del Norte county, California. J. M. Claassen.
4748.	Silver Ore—Non-ten B. mine, Esmeralda county, Nevada. J. M. Claassen.
4749.	Variegated Obsidian—East of Mono lake, and three miles inside the State of Nevada, Esmeralda county. J. M. Claassen.
4750.	Volcanic Tuff, so-called White Lava—A similar rock is used in building ovens for bread baking (see No. 4751). Found near Ktna Springs, Napa county, California. C. Hartson.
4751.	Volcanic Tuff—Used in Europe in building bake ovens. It has the property of retaining the heat imparted to it by the fuel. River Rhine, Germany.
4752.	Native Copper—Five miles west of San Luis Obispo, California. Theo. G. Bilty.
4753.	Nickel Ore—Sa'd to be found in San Benito county, D. Morgan White.
4754.	Croppings—Manzanita gold mine, Sulphur Creek, Colusa county, California. (See No. 4753.) Charles M. Tyler.
4755.	Blumens Stone, or Impure Limonite—Near Mt. Diablo, Contra Costa county, California. Volatile matter, including water, 25%; fixed carbon, 17.6%; Ash, 58%; total, 100%.
4756.	Silver from cupels copper-smelting furnace, Pelton, Pluma county, Arizona. H. M. Howe.
4757.	Copper Matte with Metallic Copper. James C. Weir.
4758.	Aragonite—Ranch of J. M. Pugh, near Smithville, Colusa county, California. W. H. Wilson.
4759.	Rich Ores—Partzite, native silver, galena, etc.—Tower mine, near Benton, Mono county, California. J. M. Claassen.

COMPTROLLER KNOX will shortly pay to the depositors of the Freedman's Bank another and final dividend of seven per cent. out of the remaining assets of that insolvent corporation. Dividends amounting in the aggregate to 65 per cent. have already been paid.

DO NOT be deceived. Insist on having the genuine Brown's Iron Bitters, made only by the Brown Chemical Co., and take nothing else.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

AMADOR

PURCHASE.—Amador Ledger, March 16: A report has been circulated to the effect that A. Hayward was likely to purchase Nevill's famous mine near Middle Bar. We understand that negotiations have been in progress with a view to the purchase of an interest in the property, but not in behalf of the capitalist named. Mr. Nevill expects to get the mill running in the course of a few days.

THE Bunker Hill mine resumed operations in the early part of the week, and the prospects are reported to be very encouraging, the quality of the ore perceptibly improving.

THE personal property belonging to the Mahoney Co., held under attachment, was sold by the Sheriff on the 13th. It was bought in by Werner & Sutherland, in behalf of the attaching creditors, for the amount of judgment and costs—about \$1,000.

THE Tellurium mine and mill near Pine Grove was attached this week, for claims aggregating over \$1,600. The late employees have commenced filing liens against the property.

FROM PLYMOUTH.—Gentlemen representing the Salt Lake M. Co. were in town last week, and left Sunday morning for Fairplay, in which vicinity they lately purchased two mines. They returned in the evening, and left, Monday, for San Francisco, apparently well pleased with the prospects of the section they visited. A. J. Burnett has struck another ledge on his property at Fairplay, which seems to be in the nature of a pocket claim. One day this week, he dug a hole, and found a small piece of rock, which yielded \$14.50 in gold. There is considerable interest being taken in the mining resources of Fairplay and neighborhood. A San Francisco company had an expert up here one day last week, in company with A. J. Burnett, who also seemed satisfied as to the mineral wealth of that region.

EL DORADO.

GOOD PROSPECTS.—Mountain Democrat, March 16: We hear highly favorable reports from the Polar and White Bear mines, at Henry's Diggings, both of which are under the management of Superintendent C. H. Watt, formerly of Sacramento. The ledges are large and strong, and give very flattering prospects.

FINE GRAVEL.—At Henry's Diggings, in the bank adjoining the Carrie Hale gravel mine, of which latter J. H. Bradley is superintendent, Roberts & Armstrong have been sluicing for some weeks in gravel, some of which has yielded as high as \$8 to the pan. The owners claim that they have \$20,000 or more in sight.

THE EL DORADO MINE.—This mine, formerly the Last Chance, is located on the north side of the Cosumnes river, opposite and on the range of the Crystal mine, and is owned by J. and M. McEvoy, O. F. Eaton, F. Davidson and B. C. Fuller, all residents of that neighborhood. They are opening up in good shape, have a large and strong ledge exposed, with a number of rich chutes, and will probably have a five-stamp mill up within the next 60 days. Superintendent Alexander, of the Crystal mine, has opened up a strong ledge of fine looking ore, and the future success of the mine is assured.

D. A. CLINE was up from Shingle Springs, Thursday, and says that within the past few weeks a large amount of fine machinery—the finest he has ever seen brought into this county—has been received at that place, to be used on Joshua Hendy's mine, at Nashville, the far-famed Havilah.

THE "COUSIN JACK" MINE.—This mine is situated at Henry's Diggings, 3½ miles from Grizzly Flat. It is owned by San Francisco capitalists, and the property is managed by C. J. Eaton, Superintendent, who has had charge of it since August, 1882. At that time the top tunnel was in 75 ft, with a 14 inch ledge of good pay ore. In sinking 40 ft the width of the ledge increased to an average of about 2½ ft and the ore improved in quality. The middle tunnel was then in 140 ft, and has been extended until it is now 325 or 330 ft in length, with a ledge that will average 14 inches thick the whole distance. Two "uprisers," of 40 ft each, have been made showing a ledge of 14 inches, some of which assayed away up in the thousands. In this tunnel, at a distance of 150 ft from its mouth, a winze has been sunk 75 ft, at which depth the ledge is 2½ to 3 ft thick, solid between well defined walls. The upper is 125 ft above the middle tunnel, and

STARTED UP.—The Lasky mill at Beveridge is reported to have started up last Thursday. We trust its period of grinding the gold out of the mines of that district may be extended for many years to come.

MARIPOSA.

INDIAN GULCH.—Mariposa *Herald*, March 16: We are building a large quartz mill here for the Gonzales M. & D. Co. The size of the mill will be when completed 32x78 ft, more than one half of which is now completed, and the machinery is nearly all in position, and in two weeks can be set in motion. The process of working the ore is M. B. Dodge's patent, consisting of a rock breaker, one pulverizer, elevator and screens, amalgamators two wet concentrators, and two dry concentrators. Mr. Dodge, who is an old miner and prospector, has given this process years of careful study, and for two years past has spent time and money in perfecting and improving it until it is as near perfection as may be, and he will guarantee to work all rebellious ores and save all the precious metal contained therein. Our superintendent, Mr. F. T. Houghton, has selected this process after careful investigation, and from his mining experience his judgment can be relied on.

MONO.

TRUE DEVELOPMENT IMPROVING.—Candelaria *True Fissure*: A resident of Clover mining district, Mono county, was in town this week, and speaks very highly of the present appearance of the Wild Rose mine. The management feels highly encouraged with the result of the prospecting now being done, and anticipates making good bullion returns for the past operations, and the coming summer's work. Quite a little village is being built at the mouth of the tunnel which includes a store, containing only the more essential articles required by the employees, of whom there are now fifteen. A town site is thought of, and will probably be located in the little valley or canyon just below the ore dump. The district has about 50 or 60 men in it already, and appearances indicate there will be a hundred before the first of May. The lumbermen are becoming active so early in the season, but now engaged in overhauling the machinery at the sawmills. Two new mills are talked of, for the purpose of cutting the excellent timber in the near vicinity, and to the southward, for use as ties in building the Carson and Colorado railroad, and other purposes.

NEVADA.

NEW QUARTZ MINE.—*Herald*, March 18: The Reward is the name given to a quartz ledge situated on the Rifle grounds, about a half mile from town. Work has been in progress about six weeks and during that time two shafts, each 70 ft in depth, have been sunk upon the ledge. A 90 ft drift connects the shafts. From the bottom of the new shaft a drift has been run off nearly a hundred feet, and a ledge of good looking rock uncovered, the vein matter being from 10 to 12 inches thick. Free gold can be seen in many places of the ore and the sulphurets contained in it of good character, although the quartz does not as yet carry any great amount. It is thought that as the ledge is developed and a greater depth attained, the rock will become more heavily charged with sulphurets. Two whipsays are at present used to do the hoisting. A crushing of rock will be had in a few days, when the prospects of the mine will be better known. S. R. Williams and B. C. Walrath, of this city, are the owners of the Reward. Eight men are employed in the mine.

DULL TIMES ON THE RIDGE.—*Grass Valley Union*, March 16: A gentleman who, within a few days, visited nearly all the towns on the Ridge, from French Corral to North Bloomfield, says there is a general complaint of dull times, which are likely to remain so through the summer season as the water supply for mining is certain to be a short one under the most favorable circumstances, as there is but little snow in the mountains, and any snowfall that may come at this time of the year will not furnish water any great length of time, as it will melt off too quickly. For the snow to be of good service in furnishing a summer supply of water there must be a good foundation for the first snowfalls of the season which have solidified into ice, and then the new furnished by the late or spring storms will remain until the heats of summer come on. Some of the large hydraulic companies, which own their own canals and reservoirs, will have water sufficient to last probably as late as August, but companies that are companies that are compelled to purchase water will hardly be able to work later than the first of June, if so long. The present season to all appearances, will not be generally profitable to the hydraulic mining business.

PLUMAS.

GREEN MOUNTAIN.—*Greenville Bulletin*, March 14: It is very fortunate that power enough should be supplied to keep the air compressor running without interruption; good progress is being made in the tunnel, the average daily advance being fully eight ft. The flow of water in the face of the tunnel has increased during the past week. This does not hinder the work any, but adds to the discomfort of the workmen. A very agreeable change is apparent in the atmosphere of the tunnel since the fan was started. After a round of holes has been exploded the air at the face is now quite clear in a few minutes, so that but little delay in resuming work is caused by the smoke. At the mouth of the tunnel a new building has been erected, covering the entrance, the fan and water wheel, and also the blacksmith shop under one roof. This was done to prevent delay or hindrance from snow.

TAYLOR-PLUMAS.—The drift running east from the winze is now in about 70 ft. As was anticipated, the ledge has improved as it is opened to the eastward, and at present is fully five ft wide. The ore looks very well, the foot and banging walls are well defined, and this part of the mine gives all indications of opening up a fine body of ore. The present method of getting out this ore is slow and expensive; it has to be carried to the bottom of the winze in a wheel barrow and there hoisted up to the tunnel by hand. As an improvement on this Mr. Bransford proposes to sink direct on the ledge from close to the mill and take power from the driving wheel to do the hoisting. This would reduce expenses very much, and open up a far larger ore body than can be economically worked from the present drift.

NEW SHAFT.—Work has already been begun on a new shaft at Crescent. The ground on which the shaft is located was taken up by C. H. Higby as an extension of the Crescent mine, and it is said that

the owners of that property will claim the ground as part of their original possessions. Should this prove to be the case, a lawsuit will be the result, as back of Mr. Higby there is money and grit, while the owners of the Crescent mine are lacking in neither. The lawyers are very lucky in mines; true, they toil not in them, yet nearly every good strike in mining is a bonanza for them.

SHASTA.

LOWER SPRINGS.—*Shasta Courier*, March 16: C. S. Jones and his father have become interested in the White mine, at Lower Springs, and have gone to work with energy and determination to fully develop this promising claim. Ore taken from the mine and worked at Waugh's anastara, yielded an amount that showed that works on the claim would result in obtaining very handsome returns. We understand that parties, "well heeled" financially, are preparing to put machinery on the ground and work the quartz in good shape. Seventeen years ago Peck & Peart put up a "coffee mill" there and scraped around a little in the quartz and "busted up." The "Little Devil" quartz mill was also tried, the machine which D. D. Harrill offered to bet he could beat cracking quartz with his teeth, but that machine was soon taken away in a wheel-barrow. There is no doubt in the world but what the Lower Springs quartz ledges will pay well when properly worked. Their depth, extent, and the yield obtained by the anastara working process, attest that they are good mines and fully justify the prompt expenditure of capital in their further development and practical working. We hope that the time has now come when Lower Springs quartz ledges are to be treated and valued at something like what their undoubted merits warrant.

SIERRA.

A NEW LEDGE UNCOVERED.—*Sierra Tribune*, March 16: A fine looking ledge that carries gold was recently uncovered on the Harlem M. Co.'s ground. This was a blind lead, and its existence was hitherto unknown. It promises to be a very important find and we shall have something further to say regarding the matter at an early date.

THE MARGUERITE MINE.—*The Marguerite* quartz mine, in this county, during the month of February, yielded \$25,600 worth of bullion, \$15,600 of which, we understand, was extracted in 14 days.

STRUCK GRAVEL.—Last Saturday a telegram was received from Superintendent Lawry saying that gravel had been encountered in the Bald Mountain Extension mine. L. Nessler visited Forest City on Monday. He reports that there is a big excitement in that town over the strike. The owners are in high spirits, and express the opinion that the assessment period is past.

Nevada.

CHERRY CREEK DISTRICT.

WITHOUT A PARALLEL.—*White Pine News*, March 17: It is no uncommon thing to see mining companies close up, in most instances pay up, but in some few cases go into insolvency, and quit business for good. In all such cases, however, the property they have been working has proved valueless, and the stockholders got tired of "putting up," when they saw no hope of finding ore. But it has been left to the Star Company to be the first to commit financial suicide in the very presence of open prosperity. With a mine that has yielded over \$3,000,000 in the past five years, with no machinery to speak of, with poor management, and prospected barely below the grass roots, it is no wonder that the managers have not been able to make fortunes out of it. But, notwithstanding all this, the Star mine to-day looks better, has more ore in sight, and promises better than it has at any time since it was opened. It looks both silly and wicked to abandon such a property. We feel certain it will not be abandoned for any length of time. The folly of its owners can hardly go to such an extent, for mining properties like the Star are not to be found every day, and the petty spite of its managers can hardly go to the extent of laying idle one of the best mines in the State.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, March 16: This mine has developed some changes of importance during the week. A distance of 12 ft has been made in extending the cast drift from the bottom of the main winze, from the fifth shaft level. It is now 22 ft in length, the face being still in quartz giving low assays. Crosscut No. 2, on the same level, shows small streaks of sulphurets yielding assays of \$30 per ton. Everything is running smoothly at the hoisting works, and all the other work is progressing well. The daily output of ore has been about 60 tons, which mill No. 2 continues to handle easily, and is doing good work meanwhile. The bullion shipments amount to \$13,344.59 for the week ending March 15th, with a total of \$24,127.34 on March account to the same date.

MOUNT DIABLO.—A small amount of \$65 ore is being stopped from the drift connecting winzes Nos. 1 and 2. Lower winze No. 2 is showing 18 inches of ore assaying \$70 per ton, at the point where the slope is being extended easterly. A slope has been started from this winze 60 ft below the third level, and has developed 15 inches of \$90 ore in ground that looks encouraging. Small amounts of ore are taken from the slope from the drift on the first intermediate level, the first level and from the Mount Diablo adit.

EUREKA DISTRICT.

AN OLD PROSPECTOR IN LUCK.—*Eureka Sentinel*, March 16: It is not often that we feast our eyes on native silver from the mines of this district, but yesterday Mike Lyons came in from the Dugout mine on Prospect Mountain with two beautiful specimens containing very silver that he had taken from near the surface. He says that there is more of the same kind to be found, and has promised to bring in a nice specimen in a few days to place in our cabinet. The history of the Dugout mine is such that had it been situated anywhere in Colorado the newspapers of that State would be teeming with glowing accounts of it. Mike Lyons worked at the Richmond furnaces a few years ago, but was stricken with lead colic and compelled to go to San Francisco for a change of climate. As soon as he recovered his health he obtained employment at the C. P. R. R. freight depot, but, pining for his old haunts, returned to Eureka, and, unable to find employment, commenced prospecting. While so employed he discovered some good looking float rock at the western base of Prospect Mountain, near where it

joins the Spring Valley range. He traced out the ledge, and, with Paddy O'Keefe as his partner, commenced running an open cut up the side of the hill. Their painstaking was well rewarded. They have since shipped to the furnaces enough ore to keep them comfortable for several years, and now have one of the very best mines on Prospect Mountain.

NOTES.—*Eureka Sentinel*, March 16: The Eureka tunnel ore bodies are holding out nobly. There is room for two or three more good tunnel enterprises on Prospect mountain. The Kirby Hill tunnel is looking very well, the face being in very favorable rock for ore. Orders are daily expected from the Silverado M. Co. to resume work upon their mines at Silverado. The number of miners that have commenced leasing mines on Prospect mountain would make a small army. There are more men employed there than ever before in the history of the camp. This speaks well for Prospect mountain mines. Messrs. Waters & Co. are hard at work in the Geraldine tunnel, which they are running to connect with the old incline of the Grant mine. They have had a lease of the property for several months past, and are sticking faithfully to their undertaking. The prospects are that they will be handsomely rewarded.

PINTO DISTRICT.

PROSPECTING.—*Eureka Sentinel*, March 16: There are several prospectors now searching for mines on Silverado, Dome and Sugarloaf mountains in Pinto district. A fine streak of ore has been discovered in the croppings of the Berryman tunnel claims, on Silverado mountain, Pinto district. M. H. Joseph and others have located some valuable claims in Pinto district, near Alhambra Hill. They have taken ore from the croppings that gave fair assays in silver and carrying a large percentage of copper.

SANTA FE DISTRICT.

A RUSH FOR COPPER ORES.—*Candelaria True Fissure*, March 16: Santa Fe district is fast opening a large area of copper mining. There are a great many prospects in that section of the country, nearly all of which are being worked more systematically and energetically this season than at any previous time. Some very pretty specimens were brought in this week, and very flattering accounts are told of quite a number of fine looking properties. Several smelters will necessarily have to be erected at an early date, each of which will cause more search to be made for copper ore, and assist the settlement of this fast becoming noted mining section of Nevada.

WILLOW CREEK DISTRICT.

THE SILVER WAVE MILL.—*Silver State*, March 14: The Silver Wave mill, at Willow Creek, is now running steadily and doing good work. J. E. Bernard, who arrived here yesterday from the Willow Creek mines, says the mill is crushing from 10 to 12 tons of ore daily. It is working ore from the Iowa mine. Elias Jones has one of his large teams hauling ore from the mine, which is about three miles from the mill, and unless the roads get very bad from late storms, there will be no trouble in supplying the mill, as there are some 200 tons of ore on the dump at the mine, and the mine is in a condition to keep up the supply for an indefinite period.

New Mexico.

MINING NOTES.—*Southwest Sentinel*, March 19: The Solid Silver M. Co. during the past week have received two wagon loads of very nice ore from their 80 ft level on the Black Hawk claim. The Colossal claim, owned by William Eckels and others, at 45 ft shows a 12 inch streak averaging 200 ounces silver. Parties from the East are examining the property with a view to buying. A very rich discovery of mineral was recently made in the vicinity of Bald mountain comprising a group of twelve claims. They lie about three miles northwest of this mountain, on the north side of a canyon known as Silver Gate, and about midway on a straight line between Bullard's Peak and Silver City. The Modoc and Phumas, two of the claims, on account of the great quantity of rich float and the richness of the croppings, has created quite a ripple of excitement among the miners of that section of country. It is called the "California" group. Two veins have been discovered on the Modoc, one running from 6 to 14 inches in width, and the other varying from 20 inches to 4 1/2 ft. The ore is a rich gray carbonate, stained with copper, and from a series of assays made from the croppings and near the surface, \$50 per ton in silver has been obtained and 40% in lead. We are assured that this is the average. A few feet from the top of the croppings large kidneys of horn silver and silver glance was discovered, which yielded an average of \$800 per ton by a number of careful assays. Several large pieces of float, about two feet from the surface were also found of immense richness, going high as \$20,000 per ton. Competent judges, who are disinterested, say that car loads of this float may be gathered on this claim. The 4 1/2 ft vein prospects \$20 per ton. On the Phumas claim a streak of rich carbonates has also been discovered, similar to that on the Modoc. There is a lace of 18 inches of rock on the claim carrying rich horn silver. On the crest of Telephone hill near by, is a contact between quartzite and granite, and the most noticeable feature is that every vein in the camp runs towards this contact. The properties are all surveyed. J. L. Holland, John M. Wright and the Dorsey Brothers are the owners. Specimens of the ore on exhibition at the office of McComas & Wright are marvelously rich.

A BIG MINING SALE.—*Southwest Sentinel*, March 14: Yesterday Mr. Clayton, a mining capitalist of Minnesota, purchased Wm. Dorsey's one-third interest in the Mother Lode group of claims in the Telegraph district, this county. The group comprises eight claims. Eighteen thousand dollars in cash was paid. The owners now are Mr. Clayton, one-third; C. P. Crawford, one-third; Newton Bradley owning the remainder.

MINING ITEMS.—We saw ore taken from the Mule mine at Pinos Altos, Monday. It is a fine, rich carbonate, carrying a large percentage in lead and assays well in silver. Embedded among the beautiful white quartz crystals may be seen particles of free gold. The claim is a promising one, and is liable to develop a bonanza. R. V. Newsham and others are the owners. W. C. Ross is taking out a large amount of high-grade silver ore from his mine in the Bald Mountain district, and will send it to John R. Magruder's smelter, on the Ivanhoe mine,

for treatment. C. P. Crawford, M. B. Hayes and R. B. Higbee have given a working bond on the Peacha, Surprise and Mountaineer mines to C. W. Watson and James Van Dyk. Consideration \$10,000. Messrs. Watson & Van Dyk will commence work at once with a good force of men. Watson was formerly superintendent of the Homestake mines in the Black Hills, and Van Dyk is also a man of ripe experience.

Utah.

REVIEW.—*Salt Lake City Tribune*, March 17: Another week of remarkably fine and clear weather has passed; it has been quite favorable for the handling of the metals. The receipts of bullion for the week ending March 15th, inclusive, were \$165,848.36, against \$154,286.41 for the previous week. The shipments for the week ending March 10th, inclusive, comprise 41 cars of bullion, 1,051,882 pounds; one car lead, 24,176 pounds, sent west; one car copper ore, 20,000 pounds, and five cars copper matte, 102,500 pounds, sent to Colorado; making a total of 48 cars, aggregating 1,198,558 pounds. The output of the Horn Silver for the week amounted to 22 cars valued at \$66,000. Yield of this company previously reported for the calendar year, 1882, \$685,500; present aggregate, \$751,500. The Ontario shipments for the week were 40 bars, of the value of \$40,920.50, as compared with \$35,051.16 for the previous week. There is nothing new with this company. The exploiting work goes forward steadily, and when completed will very materially add to the productiveness and ease of operation of the property. It was said during the week that the impassable condition of the roads had stopped the shipments of ore from the Crescent mines, and that in consequence the Park City smelter had shut down. This must have been but temporary, for that smelter is in full blast again, and reports for the week an aggregate of five cars of bullion, valued at \$9,260. It is hoped that hereafter the product will be continuous.

WASHOE DISTRICT.

MEXICAN.—*Enterprise*, March 18: The joint Union Con. east crosscut has been extended 24 ft. On the 3100 level the joint Ophir east crosscut has been advanced 21 ft.

OPHIR.—On the 3100 level the joint Mexican east crosscut has been extended 21 ft. Are repairing the bob station in the vertical shaft. Are again extracting ore from the croppings.

SIERRA NEVADA.—On the 2000 level the north lateral drift has been extended 25 ft. The joint Union east crosscut, on the same level, has been advanced 28 ft.

Idaho.

TARIFF ON ORE.—*Wood River Times*, March 14: The Hailey sampling works started up two weeks ago with a large reserve of ore on hand or contracted for; but it may not run very long as, at the present rates, it is unprofitable to ship ore out of the country. The freight from Shoshone to Omaha is \$30 per ton; Hailey to Shoshone, \$10; sampling, \$5; hauling to sampler, \$5; working charges at Omaha, \$20; loss, percent, equal to about \$10 per ton; total cost of reducing ore to bullion, \$80; add cost of extraction say, \$10; total cost of bullion in ore, \$90. In order to secure any profit to the shipper the ore will have to carry over \$100 worth of metal. None but the very richest ore will average that high, anywhere else than on Wood river; and in this section the average has been kept up to 130 ounces silver and 65% lead, the past three years, only by the most careful selection. Unless the tariff to Omaha is reduced at least \$10 per ton, it will greatly retard the development of this section, and render the shipment of our second and third-class ores impossible, unless our producers accept the contract offered them by the heaviest Philadelphia smelters last year, to wit: A rate of \$13 per ton from Kelton to Philadelphia, via the C. P. and S. P. roads.

THE SOLACE MINE.—Supt. Childs, of the Solace M. Co., in Vienna or Smiley gulch, in the Sawtooth range, came down two or three days ago, to have a brief change from snowbanks and desert ravines to bare ground, open flats, and civilization. Although rather reticent on the subject, he states that the Solace is opening up much better than he expected when he assumed charge, and believes that he will show a good mine this summer. The mountains around Vienna are now covered with 10 to 12 ft of snow; but it is settling and melting fast. As soon as the weather permits, Mr. Childs will start work on the 12 other claims which his company owns, in Vienna gulch, and some of them will doubtless be found to contain bodies of good ore, as they carry very promising croppings.

Oregon.

NOTES.—*Jacksonville Times*, March 16: The weather still continues unfavorable and there is not much prospect for a good run this season. Welch & Ross are engaged in prospecting the Barkdell ledge and are sanguine of good prospects. C. J. Howard returned from Josephine county this week, and reports miners doing comparatively nothing. Judge Hanna and Henry Klippel, Esq., went to Josephine county, Wednesday on business connected with their mining locations in that section. McKee & Dews of Forest creek are able to run about five hours daily with their hydraulic. Klippel & Keaton on Poor-man's creek are not so well favored with water. Much prospecting is still going on in southern Oregon, which will yet prove the best mining region on the coast. Several prospectors from abroad are in the vicinity at present. Mr. Thompson is still at work in Gold hill and is going down on ore that seems rich in iron. The walls are well defined and he hopes to yet strike a ledge rich in gold. The tunnel is now 150 ft long. The ore from the Wallace ledge yields very little, but McDougal & Kahler's dump near Fort Lane is yielding an ounce to the ton. The latter ledge will probably prove an excellent one, as also may some others in the vicinity. R. W. Derickson of Horsehead, Josephine county, was in town this week. He informs us that he has a large amount of ore on the dump yet, after crushing which he will clean up and make different arrangements as to working the mill. Bybee & Co.'s ditch near Waldo, built last summer, does not fulfill their expectations, and it will have to be remodeled. Consequently, they have not been able to do much work this season; but what they have done establishes the value of their mines.

Reese River Pioneers.

Many of the original locators and developers of the mines are here yet, and many of them will die and be buried here. Your genuine Reese River pioneer is decidedly a peculiar character. He was a pioneer of California as well, therefore was among the first to join in the rush to "Washoe," and soon after to Reese River. He never was able to shake off his old California miner style, and would rather live in a cabin and work at "chloriding" and "tributing" for himself, at merely living rations, than to work for anybody else for good, regular wages. Therefore it is that he is found working "on tribute" or contract in these mines to-day, for, of course, he sold out his old locations, or was frozen out of them, long ago. He still goes out in the hills prospecting occasionally, but the whole country has been so closely scoured over and investigated that his new discoveries are exceedingly rare. Old Jim Sloggers, who is a standard member of the society of Reese River Pioneers, and who declares that he was with old Reese himself when he discovered Reese river, is the most inveterate of them all. Whisky could not kill him, but has only preserved him, as it were, and he frequently sweats that when he dies the worms in the little graveyard below town will go on a three-months' jamboree. The fine, spring-like weather of the last few days stirred up the old fellow's ambition, and he went prospecting over about Yankee Blade. Yesterday he came home and got drunk.

"Struck it again!" roared he, as he tacked ship and stood his course up street, stopping every few rods to shake hands with sympathizing friends, and tell them about it. "Struck the bulkiest kind o' chloride, richer'n Limburger a foot thick, betcher ribs."

"Glad to hear it, Jim, and now see that you hold on to a good thing for once in the way, and don't let anybody enslave or freeze you out of it."

"Ha, ha! freeze me out, hey? Git ahead of old Jim Sloggers some more, will they? Not much. Got 'em this time. Located the whole dam racket myself, and goin' ter work it myself. Hain't go no thiev'in' partners this time, and don't want none."

Then the old boy wore ship, and heat to windward for his little cabin on the hillside, chuckling occasionally as he felicitated himself on that last proposition.

Col. Dave Buel was among the first of the Reese river pioneers. He laid out the town site and built the first mill. The town was named after his partner, Alvah C. Austin, a native of Plymouth, Mass., who was here with him, but who is now a partner in the Miners' foundry, San Francisco, and resident of that city. By the way, Jack Williams, the famous desperado, so well remembered in the early days of the Comstock, and who was assassinated one evening in Pat Lynch's saloon, on B street, was also from Plymouth, Mass.—*Cor. Enterprise.*

AUSTIN.—A correspondent of the *Enterprise* says: The mill of the Manhattan Company continues grinding right straight along, and grinds exceedingly fine, its present run, which commenced on the 30th of October last, being one of the longest and most lucrative it has yet experienced. About every other day it sends forth its regular shipment of silver bullion—ten bars, worth \$1,000, or more, each. The average of the ore crushed at the previous run of the mill, last Summer, yielded an average of \$350 to the ton. The ore of the present run is not quite as rich, but there is more of it, the mines showing and developing better and more extensively than was anticipated. The monthly pay-roll of the company is about \$23,000, employing many miners at the regular rate—\$4 per day—and the tributaries are generally doing well. The mining and milling operations and other business matters of the Manhattan Company are exceedingly well managed and judiciously conducted in every respect. Notwithstanding all this apparent prosperity, however, there is much grumbling about hard times. This complaint comes principally from the business men. They openly declare that although their customers have plenty of work at good pay, they do not come forward and square up their accounts as they should. The tributaries, especially, they say, run long credits and big bills, and cannot always be depended upon to cash up. When they are in bad luck, they naturally are not expected to pay. Meanwhile, good paying customers have to make up for the poor ones, otherwise the storekeepers would soon necessarily be bankrupt. This idea or principle is not new, however, here or even on the Comstock.

JEFFERSON.—A correspondent writing from Jefferson to the Belmont *Courier*, says of the prospects of that once lively burg as follows: The work of repairing the mill is rapidly pushed ahead, and the stamps will probably be dropped by the 20th of this month. Sufficient ore can be taken from the different properties under the control of the Jefferson S. M. Co. to keep the mill running for several months without further prospecting being necessary. Several additional hands were recently employed, and, unless the almost undeniable proofs play us false, brisk times cannot be far distant. Jefferson is indeed brightening up, and bids fair to soon again occupy the position that she did years ago. At any rate, we live in hopes. It is whispered that the whistle will soon again be heard tooting from the Prussian hoisting works. If the rumor proves correct, our little camp will dance to lively music.

Divers for Mining Work.

The *Engineering and Mining Journal* says: We are indebted to R. J. Frecheville, of Truro, for the following account of the first diving operation of the kind carried out in a Cornish mine: The heavy and almost incessant rains during the winter have so increased the water in the Phoenix United mines, Liskeard, that it has risen above the plunger pole, which is situated 200 fathoms from the surface. After the plunger had been working some time under water it failed to work satisfactorily. Soon after it was discovered that it required to be packed, and the question arose as to how the obstruction was to be removed, there being from 10 to 20 feet of water above the top of the pole. The manager and agents held a consultation, and decided to engage the service of a diver. This course was generally approved in the mines and was accordingly adopted. At first one diver and his assistant came to the mines and prepared themselves to perform a piece of work underground which they had never before seen. They, however, determined to make an attempt in a vigorous

The Paradise Mines.

Reports from the Paradise mines are of a highly encouraging character. Ed. Hewitt says that the Bullion of Paradise Co., in extending their drift north from a 72-foot winze, below their present tunnel level, discovered, almost unexpectedly, very rich ore. This development is of more than ordinary importance, as it shows that the rich chute of ore in the north end of the mine continues down to an indefinite depth, and as the ore body is known to be about 90 feet in length, and in several places above from 16 to 20 feet in width, it is deemed quite probable by mining men that there are equally large and rich bodies of ore where the drift is being run. There is a winze down in this chute, or chimney of ore, 14½ feet, which the company will now sink and connect with the drift above mentioned, and they will then be prepared to rapidly, and at small expense, stoop out the ore. It is gratifying to learn that the much neglected Paradise mines, which experienced miners say have every indication of being rich and permanent, are, through

Mineral Lands.

The C. P. R. Company, owners of the California and Oregon franchise, claim each odd or alternate section of land for 20 miles on each side of the located line, and when alternate sections are occupied by prior claimant, they claim the privilege of floating to the 30-mile limit. Thousands of acres of this land is mineral in character, containing known and hidden quartz and gold deposits, and being unoccupied or sparsely settled may be confirmed to the railroad without giving Government or other party notice to investigate its mineral character. The company have no right to mineral land but will take it fast enough whenever they get a chance. The only way for miners and the friends of the Government to prevent wholesale railroad grabs of mineral land in Shasta county is to organize and club together, as the miners did in this vicinity several years ago, and make affidavit as to the mineral character of the lands alluded to. By placing mineral affidavits on these sections of lands, with the character of which mining men and old settlers are familiar, the railroad company will be compelled to give due notice before they can gain possession of the ground to which, in nine cases out of ten, they have no just right. If the miners and homestead and pre-emption settlers of this and Siskiyou county are alive to their interests they will look out for themselves at a very early date. This hint don't cost them a cent.—*Shasta Courier.*

A Valuable Dry Land Grass.

Continuing our showing of forage plants which are worth trying in this State, we take up at this time a grass which is but little known in this country, and that in Texas, where it is pronounced most valuable. It has no common name which is reported, but its botanical name is *Paspalum ovatum*. It is figured in the Department of Agriculture Report for 1880, where it is described as follows: Culms from a thick perennial rhizome, erect, 3 to 5 feet high, firm, smooth, marked by fine lines; with three or four leaves from as many dark smooth joints. Leaves at the base of the culm numerous, becoming withered and torn, somewhat hairy; the leaves on the culm erect, one quarter inch or more wide, some of the lower ones a foot or more in length, upper ones shorter, gradually long pointed, smooth both sides, roughish on the margins. The sheaths are rather loose, smooth, and longer than the joints. The raceme or flowering part is usually 6 to 8 inches long, composed of from three to six spikes, which are 1 to 6 inches apart on the rather slender axis; the lower spikes are 3 inches or more in length, the upper ones gradually shorter, slightly spreading, all with a few long hairs at the base. The spikelets are closely arranged in four rows, two on each side of the narrow and mostly straight rachis, in alternate pairs. The spikelets are about 1½ lines long, ovate, pointed, crowded, and overlapping, compressed, and the margins clothed with silky hairs. The two outer or empty glumes are ovate, acute, 5-nerved, smooth or nearly so, except on the margin, which is edged with thin white hairs. The inner or flowering glumes are cartilaginous in texture, roundish, obtuse, compressed, smooth, and shining, and, under the glass, very delicately punctate. The proper palea (upper palea) is of similar texture, fits into the margin of the flowering glume, and has a thin inflexed margin, infolding the three stamens and two feathery, purple styles.

This grass has only recently been detected in this country, and seems confined to few localities. It was collected in Louisiana by Dr. Ravenel; also, later at Fortress Monroe, Va., by Dr. Vasey, and more recently by Mr. S. B. Wallis, of Wallisville, Tex. It is also a South American species. Mr. Wallis says:

This grass I consider the most valuable of all the grasses that I am acquainted with. It is perennial, and grows here all the year round, furnishing excellent green feed for stock at all seasons, except that the green blades freeze in our very coldest weather, perhaps two or three times in a winter, and then grow out again in a few days time. It increases rapidly from seed, and also reproduces itself from suckers, which sprout from the nodes of the culm after the first crop of seed has ripened. I have seen these suckers remain green for six or eight weeks after the old stalks were as dead and dry as hay; and then, when the old stalk had fallen to the ground, take root and form new plants. It grows well on all kinds of dry land. The plant with roots two or three years old form stools 12 to 18 inches across, have very strong roots, and grow in the longest drouth almost as fast as when it rains.

COMET DISTRICT is all the go and a large amount of travel to and fro is going on; teams arriving and departing every day in the week. Even the brethren at Panaca have the Comet fever and are allured from their carrot patches by the glowing accounts of the fabulous richness of the new finds being uncovered. Thus far there has been nothing discovered to get excited about, though very rich ore has been brought to town. Stick to your carrot patches, boys, and follow the advice of the church and let mining alone.

THE leaching mill at Secret canyon, near Eureka, belonging to the Geddes & Bertrand Co., is run mostly by Chinamen, and will be run entirely by Chinamen at no late day.

A PERENNIAL GRASS FOR DRY LANDS.

manner, knowing that, if their efforts were successful, much credit would be reflected on them, as it was the first time any such work by divers had been done in mining operations. The diver succeeded in packing the pole, and a signal was given to the engine-man to work the engine. It started, and the plunger-pole worked in a very satisfactory manner all night; but in the morning the shaft men ascertained that the pole had failed, and wanted to be attended to again. The diver prepared and packed the pole the second time, and continued to attend to it until the work was deemed too laborious for one man to continue to do, and the services of a second diver was called in to perform the same work as the former.

UNCLE BILLY RAYMOND writes J. Ryan that he has a very favorable opinion of Calico district. He says that he will erect a mill this spring.

CAVE VALLEY.—John Sheridan and several others left Bristol last week for Cave valley, which is now attracting the attention of the prospector. The gold rock discovered there is reported as being quite rich.

the perseverance of the Bullion Company, being developed sufficiently to keep one mill running, and it is hoped that the time is near when the bullion shipments will equal, if they do not excel, the product of the camp in its palmiest days. In addition to the developments in the Bullion mine, we learn that Nick Frayer has made important developments in the old works of the Live Yankee mine, and that the success which his energy and perseverance entitles him to is about to be realized.—*Silver State.*

THE Windsor Mill is now in complete running order. The pack trains are busy packing ore from the Mount View mine to the wagon road at the base of the hill, whence wagons haul it to the mill. There will be a plentiful supply of ore at the mill in a few days to keep it running.—*Pinal Drill.*

RODGERS' DISTRICT is excited over the rich strikes. The World Beater bids fair to beat the world. They are taking out at the rate of one ton of ore per day to each man, some ore running from \$400 to \$1,600 per ton. Each man cleans at least \$150 per day.—*Pinal Drill.*

THE ENGINEER.

Why Men Cannot Fly.

The New York *Sun* wisely concludes that this century is likely to be forever memorable for its mechanical and engineering triumphs. It is distinguished from all the centuries which have preceded it as the age of steam and electricity, of rapid transportation for human beings and their products, and for bringing all the world in instant communication, one part with another.

Other eras may have surpassed us in literature and art. Some of our metaphysical science may not be so wonderful to the future as it seems to us; but our mechanical and engineering development has been so far beyond anything of the same sort in the past, even taking many centuries together, that this century is separated from the eighteenth by the broadest gulf in the history of human progress from era to era.

Yet, with all our mechanical triumphs and our engineering achievements the *Sun* thinks that we are no further advanced in one respect than men were one hundred years ago, or a thousand years ago, except to some slight extent for military purposes. Ballooning has made no progress, and is still nothing more than an amusement of no practical value. We do not seem to be any nearer flying than men were at the beginning of the Christian era. Our modern engineers have not yet constructed a practicable flying machine; nay, they have not yet so much as taken the first step in that direction.

The London *Engineer*, which has lately discussed flying machines in a scientific way, comes to the conclusion that there is no combination of wings or arrangements of any kind which will enable a man to fly with his own strength. He lacks muscular power to practice the accomplishment in which the birds are so proficient. And even if machines are devised to compensate for that lack of power and endurance, they will not be successful unless they shall be so constructed that each pound of the machine will develop as much energy as each pound of a bird. "Not till then," says this engineering critic, can flight for man be achieved.

Because birds fly, that is no reason why man should do the same thing, even if he is able to fit to himself wings as well adapted to his body as the wings of the birds are to its physical construction. Already "the wings of many model flying machines act just as do those of the rook and other birds," whose movements are slow enough for us to observe just how they fly. For there is a great difference among birds as to the rapidity of their flight, and not only that, but also as to the grace with which they do it. They have various styles of moving through the air, some graceful, and others comparatively clumsy, just as the walk of a courtly woman differs from that of a Sioux squaw. "We have no doubt," says our London contemporary, "that if men could once fly, we should soon have as many styles developed as there are men."

We have said that the reason men do not fly is not merely because they lack wings, but also because they are not strong enough. There is no bird of flight which weighs as much as even a very light man, but there are many birds which are far stronger than men. The limit of weight beyond which the air cannot be utilized for bird flight is somewhere about 30 pounds. Nature does not produce heavier birds, and doubtless for the reason that the air is not the proper home for animals weighing more. "The conditions under which species are developed," says the *Engineer*, "are such that everything goes as far as it can go in size and speed." The roc of Eastern story it pronounces a "mechanically impossible creature."

The albatross is the largest bird in existence, and one of the heaviest. There are heavier birds with limited powers of flying, but the maximum weight of any natural flying machine which can fly well does not exceed 30 pounds, according to the *Engineer*; and the weight of the albatross seldom, if ever, exceeds 28 pounds, or one sixth that of a powerful man. But the albatross can keep its wings, 13 feet long from tip to tip, in motion for a whole day, while the strongest man would be exhausted, if he had to keep beating the air with them, in half an hour. And to fly he would need far heavier wings to be kept in motion.

After a mathematical calculation, the *Engineer* comes to the conclusion that the albatross possesses as much muscular energy as a man, and far more endurance, with which to propel the 28 pounds of its body. "We have in the bird," it adds, "a machine burning concentrated fuel in a large grate at a tremendous rate, and developing a very large power in a small space. There is no engine in existence, certainly no steam engine and boiler combined, which, weight for weight, gives out anything like the mechanical power exhibited by the albatross."

The conclusion arrived at by both of our contemporaries is that man will have to give up the hope of competing with the birds in flying.

USEFUL INFORMATION.

An Asphalt Mortar.

The *Centrobblatt der Bauverwaltung* describes a patented composition made at a factory in Stargard, Pomerania, which has for some years past been used with perfect success on the Berlin-Stettin railway for wall copings, water-tables, and similar purposes requiring a water-proof coating. The material is composed of coal-tar, to which are added clay, asphalt, resin, litharge, and sand. It is, in short, a kind of artificial asphalt, with the distinction that it is applied cold, like ordinary cement rendering. The tenacity of the material, when properly laid, and its freedom from liability to damage by the weather are proved by reference to an example in the coping of a retaining wall which has been exposed for four years to the drainage of a slope 33 feet high. This coping is still perfectly sound, and has not required any repair since it was laid down. Other works have proved equally satisfactory. In applying this mortar, as it is termed, the space to be covered is first thoroughly dried, and after being well cleaned is primed with hot roofing varnish, the basis of which is also tar. The mortar is then laid on cold, to the thickness of about three eighths of an inch, with either wood or steel trowels, and is properly smoothed over. If the area covered is large, another coating of varnish is applied and rough sand strewn over the whole. The waterproof surface thus made is perfectly impregnable to rain or frost, and practically indestructible. The cost of the material laid is estimated at not more than 10 cents per square foot, and it is stated that this price can be reduced by at least two cents for large quantities put down by experienced workmen.

TIN ROOFING, to be good, must be put on with care, well turned up and over all angles, and flashed around all openings. As it is subject to expansion and contraction, leaks are always the result if proper allowances are not made. This is provided against by a raised standing joint, which costs a little more, but pays better by lasting longer; a flat joint is cheaper, but not durable. Tin should always be painted on the outer side of the sheets before using, as the sweating from condensation of vapor causes it to rust readily. Tin roofs should be painted thoroughly every two years, and in angles every fall. Tin sheets are 10x14 inches in size, and of different thickness; sized by X, XX and XXX. XX is the best for general use, as the metal is thin, pliable, and less liable to crack under strain of contraction than thicker metal; anything thinner rusts through too easily. It is known among makers and dealers by different brands, which designate the quantity of tin actually used. Tin is bright, and of a silvery color; adheres in large, smooth flakes. Compositions of lead and tin, or zinc, are a dead smoky color, and last but a short time under the corrosive influences of salt air, smoke and acids, these being principal causes of its decay.

JAM FROM TURNIPS AND TAR.—According to the correspondent of a trade journal, it is a mistake to suppose that fruit is absolutely necessary to the manufacture of preserves. He describes a visit to a large jam-producing factory, in which he found that the work was being bravely carried on without the aid of fruit at all. Jams of various kinds were being produced before his eyes—currant, plum, strawberry, apricot, raspberry, and gooseberry. Yet neither currant, plum, strawberry, apricot, raspberry, nor gooseberry was in the building. Turnips served the purpose of the fruit. The flavoring matter was extracted from coal tar, and the resemblance to raspberry and strawberry jam was further produced by mixing the boiling compound with small seeds of some cheap innocuous herb. A common form of sugar is used, and this is the only honest ingredient of the mess. These preserves are offered as made from "this season's fruit."

ADAMASCORITE is the local name of a mineral which is said to be found in only one place in the world, and that is the State of Missouri. The company which now owns the whole quarry will transport the stone quarried to Winchester, N. H., where it is to be manufactured into such articles as are deemed salable. The stone is very peculiar in its structure and properties. Its cutting power is diamond-like, cutting away steel very rapidly, and still retaining an exceedingly fine edge.

THE RUBBER PLANT IN MEXICO.—Mexico is making a study of the culture of the rubber plant. The hardness of the plant is said to be such that its culture is exceedingly simple and inexpensive, where the climate and soil are suitable. In much of the Mexican coast region the only expense is the weeding required when the plants are young, to give them a chance to grow and strengthen.

REPORTS come from Mexico of the discovery, near La Paz, of the largest pearl the world has ever seen. It is of light color and of oval form, one inch in length and three quarters of an inch thick at its shortest diameter, and of surpassing luster. No doubt the oyster was glad to be put out of its misery, for its tenant was too big to be accommodated, and too strong to be dispossessed. For a long time the poor bivalve had been unable to close its habitation. The owner of the pearl says that an offer of a sum less than \$50,000 for his treasure would be treated with perfect contempt.

Useful Notes on Water.

One gallon of distilled water weighs 10 pounds; one gallon of sea water weighs 10.32 pounds. 1.8 cubic feet of water weighs one hundred weight; 36 cubic feet weigh one ton, equal to 224 gallons; one cubic foot contains six and one fourth gallons. [The English standard, or Imperial gallon, is here referred to.] The average daily consumption of water in towns is 16 to 20 gallons per head. In pipes, the square of the diameter in inches equals pounds weight of water per yard. Example: An inch pipe holds nine pounds per yard. One hundredth inch of rain is about one ton weight to the acre. A nominal horse power for a boiler requires one cubic foot of water per hour. Circular apertures are most effective for discharging water, since they have less frictional surface for the same area. The *vena contracta* is the best form of orifice for discharging water. The ordinary speed to run a pump is 80 to 100 feet per minute. The pressure in pounds per square inch of a column of water is the height of a column in feet multiplied by .534, or, for an approximation, one half pound pressure per square inch for each foot of height. Water, in flowing through an aperture, has a velocity equal to that acquired by a heavy body falling freely from a height equal to the distance between the center of the aperture and the surface of the water. Doubling the diameter of an aperture increases the flow four fold. A man can raise water from a well 10 feet deep at the rate of 30 gallons per minute. The approximate time occupied in discharging equal quantities of water, under equal heads, through pipes of equal length, varies from 80 for a straight pipe, 200 for a curve to 240 for a right angle.

EXPLOSIVE MIXTURES.—Explosive mixtures are sometimes prescribed by doctors not well informed in *matéria medica*. Chlorate of potash, permanganate of potash, and glycerine are some of them. A pomade of chloride of lime, sulphur, and other substances, will detonate when rubbed in a mortar. Hypophosphite of lime or soda, when triturated alone, sometimes explodes. Pills of oxide of silver are apt to decompose with a tremendous explosion. Tincture of iodine and ammonia form the iodide of nitrogen, a violently explosive substance, which, agitated with water, is nearly certain to detonate. Chlorate of potash and tannin are likely to act in the same way. A dentrifrice containing chlorate of potash and catechu has been known to explode in the mouth.

GOOD HEALTH.

How to Sleep.

Health and comfort depend very much on attention to matters that to some seem very trivial. We have sometimes heard persons complain that they did not sleep well; that they were troubled with horrible dreams, and arose in the morning weary and nervous. Inquiries as to diet, exercise and other essentials of health have often failed to reveal anything that could account for these unfavorable conditions.

It is not well in these cases to limit our investigations to the routine of a day; but we should inquire at what hour the patient goes to bed, what he thinks about usually, and most particular what position he places himself in to invite sleep? If he lies on the back with his hands over his head, there will be a half conscious sense of compression of the chest, with difficult breathing, to relieve which he opens his mouth. The air coming in contact with the throat causes dryness, and then snoring will begin. In the meantime the pressure of the viscera on the large artery, whose course is along the inner portion of the backbone, impedes the circulation of the blood, producing discomfort which manifests itself in horrid dreams. Thus the whole night is passed in a disturbed sleep, and perhaps many nights pass without one of refreshing sleep. The most unwise course under such circumstances would be to resort to the use of opium, or any other drug. The ranks of the victims of this unfortunate habit are recruited mainly from such cases as we have described. It is wonderful what control an individual can get over himself if he tries. There is no reason why a person cannot lie upon his side instead of the back, and keep his hands and arms down; then he will not open his mouth; then his throat will not become dry, neither will he snore or have bad dreams. But often he can't help thinking about his business, and his thoughts will run on for hours. This is also a habit that may be broken up. Have the will to put aside your thoughts, and in time you will have the power to do so.

We do not say that there are not other causes that habitually interfere with sound sleep, but we believe there is a remedy for each difficulty, which may be found by seeking for it.—*Herald of Health*.

A NEW USE FOR THE TRANSFUSION OF BLOOD. The transfusion of blood was successfully employed a few weeks since, in New York, in restoring to consciousness a man who had been found in his room unconscious from inhaling illuminating gas. Two physicians being called, one of them suggested the trial of the transfusion of blood. A colored man attached to the hotel consented to furnish the blood necessary for the operation, which was successfully per-

formed six hours after the man had been found, during all of which time he had been perfectly unconscious. Dr. D. C. Valentine, a well known New York physician, performed the operation, which he has himself described as follows: "After first tightly binding the arm of the person from where the blood is to be taken, and the arm of the person to whom the blood is to be transferred, an incision is made in one of the veins of the former, and the blood which flows from it is placed in a bowl; then the blood, which meantime has been thoroughly beaten to prevent coagulation, must be strained through a piece of linen into another bowl, when it is ready for placing into the arm of the patient. This is done slowly—a little at a time—by the aid of a syringe, through a puncture made in a vein in the arm, and the operation is done. It is, as you will see, simple and almost invariably effective. Of course, care must be taken to have a healthy person to draw from, as otherwise any disease might be transferred, though, to my mind, I would sooner have an unhealthy person to draw from than none at all."

A SCIENTIST ON TIGHT LACING.—Richard A. Proctor, the astronomer, once tried the experiment of wearing a corset, and thus describes the result: "When the subject of corset wearing was under discussion in the pages of the *English Mechanic*, I was struck," he says, "with the apparent weight of evidence in favor of tight lacing. I was in particular struck by the evidence of some as to its use in reducing corpulence. I was corpulent. I also was disposed, as I am still, to take an interest in scientific experiment. I thought I would give this matter a fair trial. I read all the instructions, carefully followed them, and varied the time of applying pressure with that 'perfectly stiff' bask about which correspondents were so enthusiastic. I was foolish enough to try the thing for a matter of four weeks. Then I laughed at myself as a hopeless idiot, and determined to give up the attempt to reduce by artificial means that superabundance of fat on which only starvation and much exercise, or the air of America, has ever had any real reducing influence. But I was reeking without my host. As the Chinese lady suffers, I am told, when her feet-bindings are taken off, and as the flat-head baby howls when his head-boards are removed, so for a while was it with me. I found myself manifestly better in stays. I laughed at myself no longer. I was too angry with myself to laugh. I would as soon have condemned myself to using crutches all the time as to wearing always a bask. But for my one month of folly I had to endure three months of discomfort. At the end of about that time I was my own man again."

HOW LONG OUGHT A MAN TO LIVE.—Thurloe Weed, who died the other day, was 85 years old. That in America is regarded as a very old age. It gave Mr. Weed distinction, as much as anything else, in his city. Comparatively speaking, Mr. Weed was an old man, but, in fact, he came nearer living out the measure of his days than the majority of men. There is no valid reason why, under favorable conditions, a man should not live 100 years. All animal life is found to be constituted with a stock of vitality sufficient to run it five times the period the particular animal requires to mature. For example, the horse matures in about five years, and will be dead in about twenty-five; the dog matures in about two years, and will be dead in about ten—and so on through the list; but a man who matures in about twenty years, and ought, therefore, to live 100, is dead, on an average, at 35. The failure of the rule in the case of the man does not prove that the rule is not applicable in his case, but simply that he fails to comply with the conditions of life. The lower animals come nearer complying with the conditions than man. Man wastes his stock of vitality, and is bankrupt before his term is half spent. There is nothing dearer to man, it is said, than his life, and yet there is nothing with which he is so improvident and reckless.—*Wheeling Register*.

HIGHT NIGHT AND DAY.—It is asserted by Dr. Merkel that a person's hight after a night's rest, measured before rising from bed, is two inches greater than in the evening, measured standing. On first rising, a sudden shortening takes place at the joints of the legs. The sinking at the ankle is one third of an inch; at the knee, one twelfth to one eighth of an inch; at the hip, two fifths of an inch. The contraction in hight is continued through the day by the gradual yielding of the arches of the feet and of the discs of the spine.

CONSUMPTION.—Consumption has hitherto been regarded as a disease of the lungs, which cannot be reached directly except by inhalation, and the value of that form of medication is problematical. A new theory of the disease, called the Salisbury theory, makes it one of unhealthy alimentation. According to this view, it is the fermenting of food in the stomach, which furnishes to the circulation noxious material that affects the lungs on reaching those organs. Granting the truth of the theory, we shall have to consider consumption as curable. All that needs to be done is to use only such food as will not ferment in the stomach, and to clean out the organ occasionally by a judicious use of warm water, with simple tonics before meals to aid the digestive process. A weak solution of ferrie per sulphate is recommended for inhalation to check hemorrhage in a severe stage of the disease. The idea is worthy the attention of the many who are disposed to be in the initial stages of consumption.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Eureka Planing and Smoothing Machine, 201. A Perennial Grass for Dry Lands, 206. Apparatus for Assaying Bullion, 209.
EDITORIALS.—The Eureka Planer and Smoother; Mill Sites; Taste and Odor of Minerals, 201. Passing Events; Working Low-Grade Ores; A Great Legal Warfare, 208. Assaying of Silver Bullion, 209. Patents and Inventions; Notices of Recent Patents, 212.
CORRESPONDENCE.—Saving Flour Gold, 202.
MECHANICAL PROGRESS.—The Relative Economy of Solid and Gaseous Fuel; Paper Rails and Car Wheels; Can Iron be Burned in Melting?; Steam Boilers, 203.
SCIENTIFIC PROGRESS.—Electric Excitement; The Color of Pure Water; A Triumph to Dr. Draper; The Formation of Craters in the Moon; A New Sweet Compound; Heat and Magnetism; Light of Comets; The Action of Cement on Lead Pipe; The Highest Mountain Peak; Bleaching by Electricity, 203.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 204.
MINING SUMMARY.—From the various counties of California, Nevada, Idaho, New Mexico, Oregon and Utah, 205-6.
THE ENGINEER.—Why Men Cannot Fly, 207.
USEFUL INFORMATION.—An Asphalt Mortar; Jam from Turnips and Tar; The Rubber Plant in Mexico; Useful Notes on Water; Explosive Mixtures, 207.
GOOD HEALTH.—How to Sleep; A New Use for the Transfusion of Blood; A Scientist on Tight Lacing; How Long ought a Man to Live; Night, Night and Day; Consumption, 207.
MISCELLANEOUS.—Penbody; The Coronado Mines; Low Grade Ores; Santa Fe District, 204. Reese River Pioneers; Divers for Mining Work; The Paradise Mines; Mineral Lands; A Valuable Dry Land Grass, 206.
NEWS IN BRIEF.—On page 212 and other pages.

BUSINESS ANNOUNCEMENTS.

Anti-Scale Compound—Berry & Place Machine Co., S. F.

Passing Events.

The people of this State are still anxiously looking for rain, and miners and farmers as well are deploring the fact that the expected down-pour holds off so long. It seems now almost certain that we shall have a very short water season this year, and the mining community will not be so prosperous as was hoped.

The winter may be said to be practically over, as far as the miners are concerned. Prospectors are daily starting out on their travels for the season, and from all sides we hear of parties being formed. Southwestern Nevada and southeastern California seem to present the greatest attraction for the miners of these two States. Idaho and Montana will also claim many hundreds. Arizona and New Mexico possess many attractions, and a great number of eastern people will undoubtedly join the army of prospectors this year.

Aside from what our "Mining Summary" records, there is nothing of note from the mining regions.

A RICH strike of decomposed quartz has been made in the 70-foot incline of the Northern and Southern Light mine, Patterson district. The ore is rich and plenty of it. The mine is principally owned by A. J. Severe, of Bridgeport.

THE February product of the Ontario mine, U. T., was \$153,611, and of the Homestake, of Deadwood, Terra and Highland, of Dakota, \$105,000, \$40,000 and \$42,000 respectively.

A DISPATCH from Salt Lake says: A very extensive cave is reported as having occurred in the Horn Silver mine, which is said to have damaged property to a considerable extent.

Working Low Grade Ores.

It is a conceded fact that the salvation of a large portion of the western mining regions depends more on some means of economically working low grade ores already found, than on the discovery of new and rich mines. It is more particularly the case with the older regions of this State and Nevada that the low grade ores must be made marketable before any great era of prosperity will be again seen. In European countries, concentration is always resorted to, and the ore brought up to a certain standard before being treated; but here concentration has not become universal. In fact it has been altogether too much neglected; but lately efforts have been successfully made in several localities and the merits of concentration are gradually becoming recognized.

Of course, there are other things necessary also to make a low-grade ore pay. There must be plenty of it; the locality must be readily accessible; means and charges of transportation must be favorable; economical management, and skill and knowledge on the part of superintendents and employees; and, moreover, the business must be conducted on business principles, without over capitalization, extravagance or carelessness. There is little doubt, as we are now progressing, that in 10 years from now we will be surprised that intelligent persons conducted mining affairs as they are in most cases now carried on.

It may encourage many persons with low-grade ore on hand to know that, by the use of improved devices and appliances they have, in the Black Hills of Dakota, reduced the cost of mining to 89 cents per ton, and the cost of crushing to 45 cents. Perhaps some figures in this connection will interest miners generally. A statement from Superintendent Mc Masters shows the yields, together with the cost of mining and milling, at the different mines in the Black Hills. They embrace, as we understand it, the product of all the properties from the outset of their exploitation up to July 31, 1882, as understood.

Homestake M. Co. produced.....	\$4,367,150 48
(Tons of ore milled, 684,733; average per ton, \$6.37)	
Highland M. Co. produced.....	1 175,632 45
(Tons of ore milled, 234,081; average per ton, \$5.02)	
Deadwood-Terra M. Co. produced.....	1,221,946 57
(Tons of ore milled, 249,320; average per ton, \$4.90)	
Deadwood M. Co. produced before consolidation of Deadwood-Terra M. Co.....	831,192 23
Golden-Terra M. Co. produced before consolidation of Deadwood-Terra M. Co.....	788,054 62
Giant and Old Abe M. Co. produced before consolidation with Homestake M. Co.....	72,169 34
Father De Smet M. Co., from Jan. 1, 1878, to Aug. 1, 1882, produced.....	1,974,640 36
(Tons of ore milled, 343,394; average per ton, \$5.74)	

Total product.....\$10,434,116 10
In connection with the central enterprise of this group, the following figures are significant:

Up to Dec. 31, 1879, the gross bullion yield of the Homestake Co. was.....	\$1,051,205 58
For January, 1880.....	75,509 00
For February, ".....	84,368 20
For March, ".....	90,150 23
For April, ".....	104,231 13
For May, ".....	118,468 31
For June, ".....	123,413 03
For July, ".....	128,768 96
For August, ".....	144,980 43

Total to Sept. 1, 1880.....\$1,924,769 52

Thus we see a steadily increasing production, while Supt. Mc Masters is able to show that the cost of mining has diminished from \$1.98 down to 89 cents per ton, and the cost of milling from \$1.59 down to 64 cents in the 80-stamp mill, and from \$1.22 down to 45 cents in the 120 stamp mill. Further: "The average gross yield of ore to June, 1879, was \$9.69 per ton. Since then it has been found of advantage to extract and mill all the rock between the walls of the veins. This has lowered the grade of the ore somewhat, but the gross amount milled has been increased in great proportion, while the cost of mining has been correspondingly reduced. The yield of the ore from September, 1879, to February, 1880, varied from \$4.25 to \$5.60 per ton. Since that date it has been increased by the ore of higher grade extracted from the 100-foot level, and now averages \$7.95 per ton."

From the dividend standpoint the showing is as follows:

DIVIDENDS PAID.	
Homestake—47 dividends.....	\$1,512,500
Father De Smet—21 dividends.....	540,000
Deadwood-Terra—20 dividends.....	740,000
Deadwood before consolidation.....	275,000
Terra before consolidation.....	75,000
Dividends of the group.....	\$3,142,500
Total assessment.....	400,000

A GENTLEMAN who came in from the Azusa yesterday informed us that some eight men are employed in the Azusa mining district developing a ledge there which was first supposed to be tin, but which is now believed to be nickel. In one of the claims a shaft has been sunk for some distance, and the ledge shows a width of about five feet.—Los Angeles Herald.

A Great Legal Warfare.

The Contest Between the Land Owners and the Hydraulic Miners—The Equities and Hardships on Both Sides.

The controversy now in progress between certain land owners in the interior of this State and a portion of the hydraulic miners, because of the large pecuniary interests involved, and the persistence with which it is being urged on the one hand, and the stubbornness with which it is being defended on the other, promises to become one of the most remarkable legal combats of modern times. Notwithstanding a very great deal has been published on the subject of this controversy, there still exists much misapprehension concerning its history and merits; the interior press having, through local interests, been so inclined to favor one side or the other, as to have hardly ever presented a fair statement of facts or expressed an unbiased opinion in regard to it. But as this is a question that involves many and broad equities on both sides, it requires to be discussed, as far as may be, in a calm and impartial manner. And it is just this feature of the case—the large element of right that pertains to both sides that constitutes the great trouble in disposing of it. It is the much that can justly be urged on behalf of the plaintiff and also on behalf of the defendant, that has embarrassed the courts and the juries and so widely divided public opinion on this matter. If the right were all obviously and incontestably on one side the case could have been disposed of very quickly. If it were clear, or could easily have been made clear, which party was entitled to a verdict, such verdict could have been obtained and the questions at issue met with final adjudication long ago. It is all very well for the plaintiffs in these suits to contend that the defendants are in the wrong, and *vice versa*. And it is an easy matter for the lawyer who is retained for that purpose to argue that the equities are all on the side of this client. But with the properly constituted judicial mind the case is very different. Every judge who has been called upon to hear these cases has confessed to a great deal of embarrassment in their adjudication; so much that is new, so much that pleads for the other, coming up to be considered and determined. Thoroughly informed as to all the facts, capable of analyzing the testimony and weighing the evidence, learned, impartial, and dispassionate, Judge Temple, in his findings in the case of *The People vs. the Gold Run Mining Co.*, seems so conscious of the hardship that his decision will inflict upon the defendants, that he, in this same decision, provides a way by which they may, to some extent, escape such hardship, as regards the rights and wrongs of the parties to this contest. So nearly are they balanced, in fact, that they will probably never be able to reach a final adjustment of their differences, except through such concessions on both sides as are implied in the carrying out of Judge Temple's decision: Each will have to yield, and each will have to suffer some, to the end that both may escape the very serious injury that must otherwise befall them.

That the difference between these parties really ought to be settled through the practice of much forbearance and some natural concessions becomes fully apparent, when we come to weigh the arguments advanced by each in their own behalf, a synopsis of which argument we here present for the consideration of that large class of readers presumably interested in this matter. Before proceeding, however, to give these parties such hearing, it may be well to correct certain misconceptions that seem to prevail on the subject, and to strip the latter of such superfluous and irrelevant matters as only tend to confuse and mislead.

Area and Location of Injured Lands.

Relying upon the exaggerated statements that have obtained currency through various prejudiced channels, many persons at a distance have an idea that a vast amount of land has been destroyed, and that the agricultural interests of California generally have come to be jeopardized by the debris sent down from the hydraulic mines; whereas, the injury caused by this material, actual and threatened, is confined to a comparatively small area. The quantity of land that, up to the present time, has been rendered unfit for cultivation thereby, is variously estimated at between thirty and thirty-five thousand acres, besides ten or fifteen thousand acres that have been more or less

injured, with a considerable quantity that, in process of time, must be in like manner damaged, should hydraulic mining be suffered to go on as heretofore, unchecked, and without provision being made for keeping back the heavier portions of this debris or tailings, as the mixture of sand, gravel and mud carried off by the water from the mines is variously termed. The above are the estimates of the several officers belonging to the U. S. Corps of Engineers—the farmers and the experts in their employ making the area of these damaged lands somewhat larger.

Of these lands so injured and exposed to be injured, the greater portion is situated along the Bear, Yuba, Sacramento and Feather rivers, with some little also on the American, the Consumnes, and other streams little further south; the whole of it amounting to hardly more than one half of one per cent. of the quantity of land in California that may be considered fit for cultivation.

Not All the Mines Implicated.

As only an inconsiderable portion of the arable lands of the State has been injured by these slums, so has only a portion of the hydraulic mines been concerned in causing this injury; this class being confined to those that discharge or dump their tailings into the above named rivers or their tributaries. The extensive hydraulic mining region, occupying the northwestern angle of the State, has contributed nothing toward producing this injury. The mines there outlet into the Trinity and Klamath rivers and their confluents, and as these streams, which, through the Klamath, discharge their waters directly into the ocean, are not navigable, and there is but little farming land along them, not much complaint has yet been made of hydraulic mining in that section of the State. As no injury can there ensue from the shoaling of the rivers, and there are no harbors to be filled up—no objection on this score can, of course, be urged against a continuance of hydraulic operations. It is the case, however, that the miners even there are being threatened with suits by parties owning small patches of land along these streams, which, it is alleged, have been damaged, or, at least, are endangered by the mining detritus; and it is by no means certain that this industry will escape attack should it be finally determined that the miners are liable for injuries of this kind. If it should be held that they can be stopped from working their claims, because of such slight injury done, or because of their fouling the water in the rivers, it would prove very detrimental to that region of country, as more than one half of the inhabitants are dependent on this branch of mining for their livelihood.

Not all the hydraulic mining companies that formerly sent their tailings into the rivers further south continue that practice. The Spring Valley Company, operating on a very extensive scale at Cherokee Flat, Butte county, no longer suffer the detritus from their mine to make way into the Sacramento river, as for many years at first it was permitted to do. Finding that they were causing some harm to the farming lands along Dry Creek, the outletting channel of their mine, this company several years since hought up the land so injured to the extent of some 16,000 acres, and then proceeded to so dispose of these slums, by means of dykes, ditches, etc., that they have rendered nearly the whole very valuable for farming purposes; this stuff, before so hurtful by reason of its too great accumulation on small areas, having through its proper distribution, been converted into a valuable fertilizer.

Having thus made certain needed corrections, and narrowed the field of the maleficent mines to its proper dimensions, let us proceed now to consider

The Arguments of the Farmers and Miners, Pro and Con.

Presenting the same in the following condensed form, omitting such causes of complaint as seem trivial, or seemingly without good foundation. The farmers, conceding that the miners are the rightful owners of the properties they are working, of the ditches and other appurtenances thereunto, insist upon their observing the legal maxim, that every man must so use his own as to inflict no harm upon another. They admit that the hydraulic miners have a right to work their claims, provided they do so without violating this principle of law. But this, say the farmers, they have not

done, and are not willing to do, if, indeed, such a thing is possible. In the first place, they have, by discharging the debris from their mines into the rivers and mountain streams, so fouled the water that it is no longer healthful, or fit for domestic uses. These streams, which, before hydraulic mining commenced, or at least, before it was prosecuted on its present extended scale, were comparatively clear and pure, are now filthy, and so charged with mud that the water not only causes disease, but it is unfit for drinking or for washing purposes without being first filtered, or allowed to stand for a long time and settle. In this complaint, the inhabitants of the towns along the streams join the farmers, they being even greater sufferers from this phase of the evil than people living in the country.

The next count on the farmers' list of grievances is the damage done to the land, which, in the aggregate very large, has, in most cases, been complete, laying waste entire farms, and leaving the owners without an acre of tillable land, even their orchards and gardens having, in some instances, been destroyed. And this element of destruction is still active, encroaching slowly but steadily on the low grounds lying along and adjacent to the outletting rivers, the land rendered worthless through its agency amounting every year to some thousands of acres. The land already ruined, as well as that menaced with ruin, consists mostly of rich alluvial bottoms, worth from \$30 to \$60 per acre, being of the average value of \$40 per acre at the lowest calculation.

Then, much inconvenience and loss have been caused by reason of this debris so filling in and raising the bottoms of the rivers as to produce extreme floods such as would not otherwise have occurred, and which, besides great injury to the farming lands, has compelled the residents of the towns to keep continually raising the levees thrown up for their protection, thereby putting them to much and constant increasing expense, while it tended to promote disease by interfering with the natural drainage.

This filling in of the bottoms of the rivers, besides producing a higher flood line, has tended to obstruct their navigation; another cause of serious injury not only to the towns along them and to the country adjacent, but also to the State at large. Steamers that could formerly ascend the Sacramento and Feather rivers at all stages of water are now no longer able to do so; these streams having been so shallow at some points as to render the passage of even boats of light draft difficult in the dry season, it being argued that this lifting up of the beds of these rivers, if suffered to go on, must ultimately raise them so high that they will be likely to leave their present channels and submerge the country adjacent, reducing it to a common marsh till these streams shall make for themselves new channels. In addition to the foregoing, the farmers urge many minor reasons why hydraulic operations should be stopped until such time as the miners have provided means for so effectually impounding their tailings that they will cause no further serious harm.

The Answer of the Miners

To these representations on the part of the farmers and their allies is briefly as follows: We, with a few exceptions, took up our mining claims and commenced working them before you became possessed of your agricultural lands or founded your towns on the banks of the rivers. In securing these claims we conformed to the modes of procedure established by the laws, local and statutory. At that day, mining being considered the paramount interest of the country, to those engaged in that industry were conceded by the State and National Legislatures certain special privileges, among others the right to adopt such local usages and regulations as they might see fit, and which were to be recognized as having the force of legislative enactments.

By virtue of these local laws the miners were permitted to appropriate the water running in the mountain streams, divert it from its natural channels, and, conducting it through ditches upon their mines, there employ it in washing the auriferous gravel, which, after being washed, was run off and deposited in the form of tailings in the creeks, gulches and rivers below; these privileges carrying with them, of course, the right to foul and muddy such water to an unlimited extent. Although wholly subversive of the doctrine of riparian

rights as promulgated by the English Common Law, this mode of procedure, having so grown into a well established usage, came to be generally acquiesced in and recognized as sound law by the Legislatures and Courts, both State and Federal.

Presuming upon the validity of these local laws so everywhere acknowledged, and trusting to them for protection, the miners went on, and by purchase from the general government, or by other legal means, secured their claims, and at great expense made the necessary improvements upon them, under the implied guarantee that they should be allowed to work them in the way they had been accustomed to do inasmuch as they could profitably work them in no other. These laws were in force and active when the majority of the farmers entered upon their lands and commenced cultivating and improving them, these parties being at the time well advised as to their existence and what the miners claimed under them. But, as no one at that day apprehended any great harm would result from emptying this debris into the rivers, these farmers are not to be censured for having planted themselves so squarely in the path of these damaging floods. Commencing in 1851, hydraulic mining had, during the first 10 or 12 years of its existence, been carried on in a constantly expanding, but still in a comparatively limited way, operations having been conducted by a multitude of small companies, working with imperfect appliances and using but little

APPARATUS FOR ASSAYING SILVER BULLION.

water; but as they were mostly engaged in washing the top dirt, which was loose and easily moved, these companies managed to run off immense quantities of this material, the greater portion of which lodged in the outletting streams above the farming lands and there remained until the flood of 1861-2, which dislodged and carried most of it down and deposited it on the river bottoms below. After the channels of the mountain streams had been so cleared of this impacted mass, they refilled, but slowly, a good deal of the fresh tailings from the hydraulic mines having since been transported further down, the coarser particles being left on the farming lands, while the finer, suspended in the water, were carried still further down and deposited in the shallow bays, or were floated off into the ocean.

(CONCLUDED NEXT WEEK.)

IRON UNDER STRAIN.—Prof. Thurston, testing pieces of wire cable of the Fairmount suspension bridge, recently taken down at Philadelphia, after being in use about 40 years, found the iron to be fully equal in tenacity, elasticity and ductility to the best wire of the same size found in the market. This fact, and similar results obtained by other experiments in 1878, led him to the important conclusion that iron subjected to the ordinary strains of properly designed bridges does not deteriorate with age.

The employees in the railroad shops at Sacramento struck for more time. Saturday the number of working hours was reduced from ten to eight, the compensation per hour remaining the same. A strong dissatisfaction is manifested along the entire line of the Central Pacific which is included in the order. Wages are reduced 20 per cent by this edict.

Assaying of Silver Bullion.

The pieces of apparatus described in this article have been in use for some time at the laboratory of the Pennsylvania Lead Co.'s works, and have been found to give good working results, and to be simple and convenient. The description is by F. C. Blake, Mansfield valley, Pa., who read it at a meeting of the American Institute of Mining Engineers:

Steam Bath.

This steam bath is shown by Figs. 1, 2, 3, and 4. It is made of sheet copper, about one twelfth of an inch thick, the joints being brazed, and is used for heating the bottles in which the silver samples are dissolved, previous to the fineness determination by the Gay-Lussac volumetric method, for heating the flasks in which the gold parting is made in assays of bullion, or in general assay buttons and for general analytical work.

Fig. 1 shows a plan of the bath. The orifices, marked *a*, are made of the proper shape, hold the silver assay bottles in an inclined position, the necks resting on the raised flanges, *e, e*. There is described in Percy's volume on *Gold and Silver*, part 1, page 289, a bath for heating silver assay bottles. It has this advantage, however, that the bottles stand erect, and there is a slight danger that some of the fine spray arising with the evolution of nitrous oxide during solution of the silver may be projected from the bottle, or upon the stopper neck.

rich, and has proved to be a great convenience in making silver fineness determinations by the Gay-Lussac method. The bottles are excluded from the light, and there is no difficulty in obtaining a perfectly clear solution, when the bottles are shaken for two minutes. If more convenient, the small engine could be replaced by a crank, connecting with a line of shafting, but I think the engine to be preferable, and to be a great improvement over hand shaking, or the shaking case, as often arranged, with springs above and below the case.

We have found that the Gay-Lussac method of volumetric assay is the most reliable and convenient for determining the silver fineness of bullion that contains but a small percentage of copper, or other impurities. The Stas pipette is the best form for convenience and accuracy. The arrangements for determining the temperature of the salt solution, when assays are made as described by Sire and others, are not reliable in general work, unless more time and care are used in making corrections than would be needed to make a determination of the value of the salt solution upon fine silver with each set of assays. This latter method is probably the better one. With each set of determinations one should be made upon pure silver, from which the strength—whether above or below the normal—of the salt solution can be determined. All the assays of any set, including that of fine silver, are made under exactly the same conditions, and the results should be reliable if the test silver is pure. There is no difficulty in preparing pure silver if care is taken to obtain a pure chloride. If silver, 998 or 999 fine, cannot be used to dissolve for precipitation as chloride, it is best to redissolve the silver first reduced from the chloride and reprecipitate. The assays, made by different persons, of silver bullion bars, often do not agree exactly, especially when the bullion contains a considerable percentage of impurities. One cause for the different results is due to the sampling. The bar should always be sampled, when it is possible, as it is poured, a small portion being taken with a sample ladle, as soon before the bar chills as possible, and granulated in water. There will be sometimes a slight difference between the poured sample and one which is cut from the surface of the chilled bar, due to molecular changes in the alloy as the bar cools, especially if the bullion is quite impure and cools slowly. It is evident, I think, that a sample, properly taken when the bullion is poured from the cupel test, or from a crucible, is the sample which will most accurately represent the bar.

Sawtooth District.

Large Quantities of Ore.

The more promising mines in Sawtooth District are situated not far from Sawtooth city, on Beaver Creek, Lake and Eureka Creeks. The belt is mostly within a diameter of six miles, and many of the mines within the circuit are well developed.

The Silver King, owned by Kelly & Co., is a property of considerable merit, as is also the Pilgrim, in Bear gulch, and the Sunbeam, near by. Across the divide is the Wire Silver, located in 1879, which has always been regarded as a bonanza. The owners have developed the mine steadily, and the past summer shipped nine tons of the ore to the Buffalo mill in Atlanta, which netted \$1,700 per ton, and as this was not considered the full value no more ore was shipped. The owners are practical miners of many years' experience, and have expended some \$4,000 in developing the property by tunnels and incline shafts upon the vein. Taking the full width of the ore it will average 600 ounces in silver to the ton, and \$200 and upwards in gold. Near by is the Comstock, opened by an incline shaft 130 feet deep, which shows a four-foot vein at the bottom encased in permanent walls. Considerable ore has been extracted, and is now upon the dump, which will mill 300 to 600 ounces in silver per ton. The vein is uniform and rich from the surface down, so far as explored.

Next above is the Silver Bow, owned by the same parties, and an extension of the Comstock. This location has ore upon the surface the entire length of the claim. The vein is eight feet wide, mostly ore sulphates and antimonial silver predominating. The vein formation is from 20 to 25 feet wide. Adjoining the Silver Bow is the Comet mine, owned by Capt. Wooster, and being developed by a tunnel. The ledge is 20 feet wide, with high-grade ore all through it.

Next above is the Atlanta, owned by J. D. Murphy, and a very valuable property, as is also the Lucky Boy near by.

There will be a large quantity of gold and silver ore shipped from the above mines next season. The Sawtooth country has been favored with a mild winter, and very little snow now remains. Miners in from that section say dust will be flying there in a few weeks.—*Wood River Times*.

Shaking Engine.

Fig. 5 gives an elevation of a small upright engine, which has a rod, *c*, running through the packing gland, *d*, in the upper cylinder head. A box, *B*, is screwed to the rod, *c*. This box is made to hold nine silver assay bottles. A piece of sheet rubber is fastened upon the bottom of the box, and also a sheet to the under side of the cover, *f*. The cover, *f*, is clamped down tight upon the bottles by the hinged holders, *e, e*, which are held in place by a rubber band. In this way the bottles and their stoppers are held firmly in place, and will not be disturbed by the shaking. This small engine, as arranged for shaking the silver assay bottles, was introduced by Mr. E. F. Eu-

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Olan and Old Abo Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALIDE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x30. BOILERS of every form, made of Pine from Works C. H. No. 1 Flange Iron, or Oils Steel. Workmanship the most careful. All Rivets Hand Driven.

273,923.—CAR AXLE BOX.—C. M. & R. M. Wood, Healdsburg, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PORTABLE TANK AND PUMP.—Nicholas Virelich, Stockton, Cal. No. 274,060. Dated March 13, 1883. This is a combined portable tank and pump. It consists in a tank of peculiar construction, mounted on low wheels and having combined with it, and inserted within it, force pumps at each end, the whole machine being adapted to be drawn from place to place. Under the tank is a small furnace. One of the most important uses of this device, and that to which it is more particularly intended to be applied, is an insect destroyer and exterminator. It can be filled with the compound necessary to sprinkle the plants and trees, and be wheeled among them with ease and the liquid thrown upon them. The furnace and upright flue may be made to keep the contents warm. If the liquid be of such a nature as to injure the plants if left upon them, some of the compartments may be filled with it and some with pure water, which latter may be used to wash off the plants. If the device is used in cold weather, the liquids may be warmed, and when the trees are sprinkled with it the insects may be induced to come out, when they may be destroyed.

WATER-WHEEL BUCKET.—Charles D. Smith, Amador City. No. 272,592. Dated Feb. 20, 1883. This invention relates to a new and useful bucket for water wheels of that class which have their rims formed with, or have bolted or secured thereto, flanges or buckets, which receive the impact or force of a stream of water under pressure. The invention consists of a hollow or chambered bucket, provided with a central opening to receive the water, and separate and distinct discharge opening at the ends through which to discharge it outside of the plane of revolution of the wheel. The object of the invention is to utilize the entire body or stream of water by so receiving and directing it as to avoid all splash, and cause it to exert its force to the best advantage. The object may be better seen by a brief reference to the points to be observed in the construction of wheels of this class. In the formation of these buckets or flanges, two main points have heretofore been considered. The first is the impact of the stream, and the second is discharge. A good surface may be presented to the water, but the bucket may be so constructed as to hinder its discharge, which, by not being readily freed, retards the progress of the wheel. In like manner, the buckets may free themselves easily, but may not receive the stream to the best advantage. To these two points a third may be added—namely, the splash. No matter how readily the buckets may free themselves, there must be more or less splash on account of the force with which the water is directed upon them, and this splash not only takes away from the resulting or continued force of the water, but is an actual hindrance to evolution. In the construction of this bucket, this inventor claims that he gains all the advantages described in receiving and discharging the water and avoiding all splash.

PISTON WATER METER.—Frank Walker, Tombstone, Arizona. No. 272,607. Dated Feb. 20, 1883. This invention relates to a new and useful water meter of that class in which reciprocating pistons work in a cylinder of known capacity. The invention consists in a novel valve and valve chamber, and the arrangement of parts therein whereby the pistons are operated and the valve reciprocated longitudinally, and it further consists, in connection with the valve and valve chamber, in a slotted connecting rod between pistons, and an intervening lever valve whereby the strokes of the piston are transmitted to the register.

WHAT gives a healthy appetite, an increased digestion, strength to the muscles, and tone to the nerves? Brown's Iron Bitters.

Notes From Eureka, Nevada.

[From Our Regular Correspondent.]

Since a change has been made in the Albion management, a feeling of greater security has taken the place of distrust, and people here believe that under Mr. T. J. Read's management the mine will be made to work out its own salvation. Since the Albion mine was shut down, I notice that a large number of Ruby Hill miners have either started out among the neighboring hills to

Prospect Mines for Themselves, or have leased those of other persons and commenced work upon them, hence I presume that out of our troubles will come some good.

Great surprise has been manifested at the drop in Eureka Con. stock since an assessment on it was announced. It is not generally known that there has been very little change in the output of the mine during the past 18 months, but such is the case. The assessment, I judge, was levied for the purpose of paying the balance on the new machinery, which works smoothly and with very little hindrance. An accident that occurred yesterday to one of the men in the Locan shaft, which happened while the men were shifting the hydraulic pump, was not due to breakage, or anything that has or will have the effect of stopping the regular working of the machinery. The shaft is being carried down with usual regularity, and when it reaches the depth of 1,200 feet, a station will be cut, and a new level run out under the old works; then I believe that Eureka Con. will take a new lease of life.

At the Richmond Mine

I saw some splendid-looking ore on Friday last, and was told that it would work over \$400 per ton, three-fourths of that amount being gold. There are no large bodies of this quality of ore, but they are often encountered.

At the Eureka Tunnel

The output of ore at present is at the rate of eight tons per day. The average of quality is about the same as usual. During the past week a raise has been made from the old south drift, main tunnel level, from a point where the first ore body was discovered. This is now in similar ore to that. The body, as far as developed, is about four feet thick and ten feet wide. It gives promise of making into a good-sized chamber. The engine shaft, 100 feet west of this point, is down 75 feet. It is still in very favorable limestone carrying small seams of ore. The No. 3, west drift, 105-foot level, which is to connect with it, is in 30 feet; also is in very favorable limestone carrying small seams of ore. The Addison chamber, just beneath this point, is producing some very rich ore, also a considerable quantity of lime rock so impregnated with metal that the mass is shipped for second-class ore. Some beautiful-looking carbonate ore is coming from the south drift, 105 level, and from points just below it. It makes in small seams and hunches. These, however, may concentrate at greater depth into one larger body.

The "Silver Connor" Mine,

On the west side of Prospect mountain, is still looking well. This is a property that in the hands of a wealthy company would be made to pay good dividends. There is a neat little hoisting engine at the main shaft, which is down 350 feet. It is of a capacity to prospect the mine to a depth of 600 feet. From the bottom of the main shaft is a drift run to connect with the main ledge, which was followed down 45 feet to where it makes a break. Above the break is a chamber about 25 feet high, and 10 or 12 feet wide, already worked out. In approaching this there still remains a fine looking body of quartz four feet in thickness, that will work at the rate of \$200 per ton. Above and all around this are several holes, worked through in ore, and feeders appear to be going off in every direction from it. From this level the winze is continued down 75 feet in ledge lime rock, and from the bottom of it a drift has been run in a southwesterly direction several feet to where the ore is again coming in on a well defined wall. Here, also appears the best possible signs of rich ore—iron and copper stains. Northward from here is also good evidence of the ledge making downwards, a winze down about eight feet being full of ovals containing rich, soft, yellow carbonate ore. On the foot level is a fine body of low grade ore, 25 feet wide by 30 thick, which rises, as shown by an incline winze, some 75 or 80 feet towards the surface. This will work from \$30 to \$40 per ton, and throughout the mass appears small pockets of very rich ore, showing in places free gold, which is not of frequent occurrence in this district. There is exceedingly little lead in the Silver Connor mine, the ore being somewhat of a milling nature. It carries three fourths of its metallic value in gold.

The Williams Mine.

Which adjoins the Silver Connor, is a property fully its equal in value, and has exceeded it in point of production. At present there are only four men at work in it. They are employed cleaning up an old stope at the 130 level, the last shipment of ore from which worked at the the furnace \$80 per ton. The ore from the mine usually works from \$94 up to \$130 per ton, its principal value being in gold. The mine has been opened to a depth of 350 feet, and has paid

expenses from top to bottom. The fissure in places is 30 feet thick between the walls. This property was bonded for sale to an English company a few months ago, but the sale was not consummated. Negotiations failed in this case, like in many others, as I hear, because of an insufficiency of blood money. That such a goulshish system has been practiced here, the most glaring proofs exist and show; and if intended purchasers would send special agents to Eureka, who would make it their business to inquire privately into the character of their confidential agents, they would not place the most implicit reliance on their reports. The Continental and Independent mining claims, lying immediately north of the Golden Rule series of mines, were sold recently to Mr. J. Kincaid Smith, of London, England. The consideration is not known to the public, but is supposed to be about \$10,000.

The Seventy-six Mining Company

Have bonded the Eureka, Keystone, Seventy-six, Clipper, Stella and Uncle Sam claims, all situated in New York canyon to Dr. Francis D. Mueller, of San Francisco, for \$100,000. Many shipments of very high grade ore have been made from this property. Large quantities of secretions from the Richmond furnaces, that in years past have been thrown over the slag dump, are now being resmelted at a good profit to the company. Large masses of this have the appearance of raw ore from the mines. Smelting operations at the Richmond furnaces were never conducted with such intelligence and economy as at the present time. The feed floors, which were comparatively bare 18 months ago, are not alone covered from one end to the other with custom ores, but the yard is so crowded with the same as to scarcely allow room for the haulers to pass. I should not be surprised to hear that the company will start an additional furnace at an early date.

Good reports are coming in from

Secret Canyon District.

New companies are to be formed for the purpose of working mines in that locality. Several new locations have been made during the past two weeks in Pinto district, particularly at a point between Silverado mountain and Alhambra hill, where some very fine croppings have been discovered. Assays run from \$15 up to nearly \$500 per ton in silver. The low grade ore also carries 25 per cent. of copper. It is difficult to say at present for which of the two metals the claims will be the most valuable. Work has been resumed upon the Sweet-water mines in White Pine district, owned by a wealthy New York Co., represented by Mr. Eugene N. Robinson, of that city. He appears to be a careful manager, and with his assistant, Sam. Paul, a thorough going miner of many years practical experience, I have no doubt that operations upon these properties will be attended with success. M. H. JOSEPH.

News in Brief.

THE new two-cent stamp will bear the profile of Washington.

HUGH J. MOHAN has been appointed Secretary of the new Labor Bureau.

It has been decided to erect a crematory in Chicago to cost \$100,000.

PENNSYLVANIA farmers are paying a reward for the English sparrow's head.

THE Mare Island Navy Yard employes will commence working ten hours a day on and after Thursday.

THE French Government will soon introduce a bill in the Chamber of Deputies for the relief of distressed working men.

SOMETHING unusual in the brief history of Wood River is the remarkably early spring and open season that is now experienced.

A CATTLE owner of Texas is about to inclose a pasture with 50 miles of wire fence, 60 miles miles east of Laredo, along the line of the Texas Mexican Railroad.

THE United States steamship *Ranger* is all ready to return to the Southern coast and resume surveying there. The injuries she sustained from striking on a rock have been repaired.

SECRETARY TELLER has requested the Secretary of War to detail a military guard for protecting the Yellowstone Park property. Secretary Lincoln promised to comply with the request.

THE distillers of grapes and wine in the Los Angeles Internal Revenue District are 38 in number. Of this amount, 15 have closed up business for the season, and 23 are still going, but are nearly ready to close up.

MAX THOMPSON, the young train robber who assisted at the robbery of the train at Austin, Texas, a few days ago, was captured and jailed. All four of the young rascals are now in jail. The youngest is 13, and the eldest is only 16.

THE people of St. Louis are apprehensive of a cholera epidemic during the coming spring. They had cholera in 1849 and 1866, in each case preceded by high waters in the Mississippi, and another 17 years have come about.

CHEAP ORE PULVERIZER.—There is for sale in this city, as will be seen by our advertising columns, a second-hand Rutherford Pulverizer, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it.

No Whiskey!

BROWN'S IRON BITTERS is one of the very few tonic medicines that are not composed mostly of alcohol or whiskey, thus becoming a fruitful source of intemperance by promoting a desire for rum.

BROWN'S IRON BITTERS is guaranteed to be a non-intoxicating stimulant, and it will, in nearly every case, take the place of all liquor, and at the same time absolutely kill the desire for whiskey and other intoxicating beverages.

Rev. G. W. RICE, editor of the *American Christian Review*, says of Brown's Iron Bitters:

Cin., O., Nov. 16, 1881.
Gents:—The foolish wasting of vital force in business, pleasure, and vicious indulgence of our people, makes your preparation a necessity; and if applied, will save hundreds who resort to saloons for temporary recuperation.

BROWN'S IRON BITTERS has been thoroughly tested for dyspepsia, indigestion, biliousness, weakness, debility, overwork, rheumatism, neuralgia, consumption, liver complaints, kidney troubles, &c., and it never fails to render speedy and permanent relief.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinkley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Smelting Copper Ores in Mexico.

Metallic copper is a product of native metallurgy in various parts of Mexico, and by somewhat varied methods. While recently examining copper mines in the State of Jalisco, Mr. Walter B. Devereux, E. M., of Globe, Arizona, had an opportunity of witnessing Mexican copper smelting by a process which is interesting from the fact that a fine quality of copper is produced from sulphurous ores in these metallurgical operations, and apparently without excessive loss. Mr. Devereux described the process at a recent meeting of the American Institute of Mining Engineers:

The process was carried on in buildings which were part of a plant erected by an American more than twenty years ago for the purpose of smelting and working copper. After a few years, this man met with accidental death, and the works have been but little used since. Located in the center of a high range of mountains, far from any town or seaport, and inaccessible except over difficult mule trails, these substantial buildings, filled with furnaces and heavy machinery, are a strange sight to be met with in one of the least advanced of Mexican mining regions. Under the same roof with English reverberatory furnaces and calciners, the crude Mexican furnaces yield a few small cakes as a daily product. The ore comes from a large vein not far distant, and consists of a quartzose gangue, containing about five per cent. of metallic copper in the form of copper pyrites (chalcopyrite). This is pounded by hand until it will pass through a sieve of rawhide with one quarter inch holes. It is then subjected to a rude concentration in a trough through which water is flowing. The concentrated product yields, when smelted, about thirty per cent. of copper. It is first roasted in one of the old calciners in the works, although when necessary the Mexicans construct smaller furnaces, which answer the same purpose. After roasting, the ore is smelted in, or with, the furnace shown in the sketch, which constitutes the peculiar feature of the process. This furnace consists essentially of a pair of air channels or long tuyeres, constructed in the top of a mass of rude masonry, with a bellows at one end, and what answers to a crucible at the other. In detail, these stone channels are about seven feet long, slightly conical, and sufficiently raised at the back to allow free motion for the bellows. The fire ends are terminated by nozzles about eighteen inches in length, and two inches in diameter at the outlet. The ends of the nozzles come nearly to the edge of a circular basin, about eighteen inches in diameter and three in depth at the center. The basin is simply a depression in the earthen floor lined with the ashes of the *encina*, a species of oak. The ashes are rammed in moist, and then a smooth and true spherical surface is formed by a man stamping quickly around the basin with leather sandals on his feet. This basin is repaired, when necessary, in the same manner.

For each tuyere there is a round bellows about three feet in diameter, which is attached directly against the stonework at the back. The construction is similar to that of an American round bellows. The back of the bellows is fastened to an upright frame, which is hinged at the bottom, near the floor, and is provided with a cross-piece at the top for a handle. Each bellows is worked by a single man, who stands on a raised platform, and takes a single step backward and forward at each blast. The blasts are given nearly alternately, and the two currents are directed by the nozzles toward the center of the basin.

When smelting is to be commenced, a green pine pole, about ten inches in diameter, is laid across the basin in front of the nozzles. The fire end of this is supported by a roller, so that it can be moved up easily. Pine charcoal is piled upon both sides of this over the basin, and plates of foul slag are laid across from the nozzles to the charcoal. By these contrivances a greater concentration of heat is obtained. When the fire is well lighted, ore is placed on that part of the charcoal outside of the log, and coal and ore are afterward added sufficiently fast to maintain

the compact character of the pile. By this means the blast is prevented from breaking through with force and blowing the ore away. The blast is quite powerful, and the flames are constantly tinged with green. The *encina* makes a stronger coal than pine, and better for shaft furnaces, but it snaps too much for this process. By the time the ore has worked down to the bottom of the log, it seems to have agglutinated, and the melting copper and slag commence to drop at once. The whole of the smelting seems to take place before it settles into the basin, as after that the surface is almost constantly covered with charcoal. The log seems to be an essential both for controlling the force of the

blast, and for supporting the charge so that it is acted upon gradually, but with increasing power. When the basin is nearly full of slag the blast is stopped and the coal scraped away. The slag is then removed in plates as it cools, the only implement being a round pole, which is slipped under the edge, and then carefully lifted up with the cake balanced upon it. If the cake of copper is not large enough, smelting is resumed, and when sufficient copper has accumulated, the slag is removed as before, the dust blown off with a bamboo tube, and the copper allowed to cool in the basin.

It is said that 300 pounds of ore can be smelted in one furnace in four hours, but I

from the surface of the copper. A glance seemed to satisfy him, and, nodding to his assistants, he turned to me, and said with a very tragical air, *yo lo garantizo* (I guarantee it).

The cakes are made of the desired size, and allowed to cool in the basin until perfectly solid. Those intended for kettles are sold as they are, while those intended for sheets (about 125 pounds weight) are rolled in the mills of the old works. They seem to roll without flaws or cracks, and to produce an excellent product for sugar pans and stills. This rolling mill is a curiosity. The mill first sent out soon broke, and the American who inaugurated the enterprise recast the rolls and pinions of solid bronze of such strength that

MEXICAN COPPER SMELTING FURNACE.

THE SOUTHERN EXPOSITION BUILDING.

think that a considerably longer time is required. The cakes are made of forty to fifty pounds weight.

The quartz gangue separated in concentration is used as a flux. The slags are very basic, but are well fused, and seem to contain a little metallic copper.

It is interesting to note that in the rude appliance described we have all the principles involved in a shaft furnace: the gradual supply of ore and fuel, which gradually pass through increasing degrees of heat to a zone of fusion; the subsidence below into a receptacle where the metal and slag separate; the bellows and tuyeres; these are all the essentials. If in this furnace we simply remove the log, pile a few bricks around the basin, and cut an outlet at the bottom, we have at once a type which can by simple amplification, develop into our most complete shaft furnace.

The cakes of copper produced are soft, and

The Southern Exposition.

Frequent improvement on machinery in use, the introduction of new machinery for new purposes, and the rapid expansion of our manufacturing industries, seem to require periodical National Expositions, in which improvements and new appliances may be exhibited. Selling manufactured articles by sample, through the agency of commercial travelers, is now a well-settled custom of our country; but the maker of machinery and heavy implements cannot so conveniently show his samples, and the periodical exposition is, therefore, becoming a necessity to him.

The local Exposition has served a good purpose, and within its limits will continue to do so; but the easy and rapid transportation that now brings all parts of the country together, and the consequent extension of successful business enterprises into every city and every quarter have given greater scope to these representative exhibitions, and made a periodical National Exposition one of the great requirements of American industry. With that quick adaptability to surrounding conditions and new requirements which characterizes our people, this new form of exhibition has at once drifted into the proper channel. Paris may be France, but no city on this continent can be America. Our territory is too large, and the several sections of the country too well defined in their interests, their power, and their character, to leave any one city the great center which must draw to it every undertaking of conspicuous magnitude. By common consent the National Exposition is becoming a movable industrial feast, as to its location, with regular periodicity as to its time.

It had been thought that two or three years' preparation was necessary to an exhibition like that proposed at Louisville, but the Southern Exposition, to open there on August 1, has already demonstrated that where there is a strong will in such things, there is a quick way. When the project was definitely proposed, without any delay, a popular subscription furnished all the means required. An organization was promptly effected, the work of preparation at once begun, and already so much space has been engaged in the machinery apartment that the managers are compelled to extend their exhibition space beyond the original thirteen acres of building.

The engraving gives a good view of the extensive building in which the Exposition is to be held at Louisville. At highest elevation on Fourth street the building is 75 feet, but it is over eight times that wide, and it is twelve times that long. On each of the four sides will be a handsome entrance, and at each corner of the building there will be ornamental towers. Around the interior of this building runs a gallery, the length of which is over 3,000 feet, or over three-fifths of a mile.

The ent shows four courts; each contains half an acre. These are principally for light and ventilation, though they will be handsomely ornamented and used possibly for refreshment stands.

To the north of the building lies Central Park, containing 18 acres, and a magnificent growth of forest trees. This park will be under the management of the Exposition Co., and it will add greatly to the pleasure and comfort of all visitors.

Street cars pass out Fourth street on the east side of the grounds, and out Sixth street on the west side, and in this way the Exposition can be reached by a few minutes' ride at a cost of five cents. Both these streets, it is expected, will be illuminated by electricity. Within the building every comfort will be provided for visitors. Waiting rooms, reading rooms, telegraph offices, post-offices, ticket-offices, will all be conveniently located.

The report of Superintendent Regua, of the Chollar mine, states that the work done on the 2900 level proves that the precious metal does not exist there.

Persons just down from Boise City say three stages leave there daily for Wood River. The stages are nearly always loaded with passengers.

CORRESPONDENCE.

Keep the Slickens in the Mountains.

EDITORS PRESS:—The advantages of irrigation on the red foothills of the Sierra Nevada are well illustrated here about Smartsville, where are to be seen hundreds of acres of alfalfa, clover and other cultivated grasses kept green and growing the year round through the skillful application of a moderate amount of water. A little below the town Messrs. Pierce, O'Brien and McGanney own a large tract of land situated in the scrub oak belt that borders on the rolling prairies, which, subsiding toward the west finally sink into the timberless valley of the Sacramento. This land is not particularly rich, possessing the red, Edom-like soil, common on this west-lying slope of the Sierra. Yet, with moderate irrigation and careful tillage, it has been made to produce heavy crops of grain and vegetables of all kinds, the hay lands being mown several times every year. A large number of horses and cows are also pastured on this land, besides a good many hogs, fed in part on the alfalfa and clover. The animals kept here are, for the most part, of choice breeds, some of them very select.

While the profits realized from this land are sufficiently large to make it a good investment at the rate of \$100 per acre, unimproved land equally good commands about here only from \$5 to \$10 per acre. This land never disappoints the owner. Be the rainfall excessive or insufficient, there is no failure of crops, there being always snow enough in the mountains to afford plenty of water, the element on which the crop wholly depends. There are in this region no storms or frosts, no rust or blighting winds to hurt. With enough of this muddy water, for such it is, the success of the farmer, the orchardist, the horticulturist and the vintager is assured, nor does it require such a very great deal. Mr. James O'Brien, to whose charge this business has been committed, informs me that the quantity of water required for irrigation, after the first few seasons, becomes every year somewhat less. The owners of this property have for many years been engaged in hydraulic mining at this place; the water employed for irrigation being such as has already been used for gravel washing. Before being conducted upon the land, however, it is retained for a time in reservoirs, or run for a considerable distance in ditches, whereby the coarser material held in suspension is allowed to settle. Though still rather turbid, it answers well for irrigation, better perhaps, than if it was perfectly pure—the fine particles it carries being valuable as fertilizers. Conveyed upon the land in large quantities as it issues from the miners' sluice, this stuff becomes an agent of mischief, as witness the harm worked the lands along the banks of the Yuba further down.

Smartsville

Is probably the most pleasant mining town in the State, rendered so, mainly, through the extent to which the inhabitants, by means of irrigation, have improved and beautified the grounds about their dwellings. The most of the residents of this place have not only orchards and gardens, but, also, patches of cultivated grasses sufficient to keep a cow or two. The homestead of Mr. O'Brien comprises 10 or 12 acres, a part planted to choice fruit trees, vines, etc., and a part consisting of irrigated pasture and hay lands. Mr. Daniel McGanney has an equally large and attractive place, it being the finest to be seen any where in the mining regions of the State.

Coming from the mountains, one catches glimpses of Smartsville a long way off. So seen, from a distance, these patches of verdure about the place, and the green fields further down, are a pleasant and refreshing sight, especially in the summer, when the red dust lies deep on the highway, and the whole country is burned to a crisp.

In such use of this turbid water from the mines, we have an example that ought to find extensive following, there being many places along this great piedmont country where it could be repeated with good results all round. Properly distributed, this water, instead of causing injury to the already fertile valley lands, would cover these russet hills, now so arid and barren, with orchards, meadows, and fields of grain.

H. DEEROT.

Smartsville, Cal.

THE New York & Utah Mining Company are about to begin operations again. Mason M. Hill, manager of the affairs of the company in Utah, lately arrived from the East, and is perfecting plans to start the smelter belonging to the company. This smelter is located in the valley at the foot of Bingham Canyon.

ROGERS' DISTRICT, A. T., is excited over the rich strikes. The World Beater bids fair to beat the world. They are taking out at the rate of one ton of ore per day to each man, some are running from \$400 to \$1,600 per ton. Each man cleans at least \$150 a day, says the *Pinal Drill*.

WOOD RIVER reports everything well and promising. When the season opens and the railroad gets through, the output of bullion will begin in earnest, and will not slack.

A REPORT from the diamond mines at Kimberly, South Africa, says that last year diamonds were shipped to the value of \$20,000,000.

A Great Legal Warfare.

The Contest Between the Land Owners and the Hydraulic Miners—The Equities and Hardships on Both Sides.

(Concluded from our last issue.)

Inactivity and Remissness of the Farmers

Warned by the mischief resulting from the flood of 1861-62, and incited by its partial repetition every year thereafter, these injured land owners, it would naturally be supposed, would have hastened to adopt decisive and effective measures for preventing the miners from further dumping their tailings into the creeks and rivers above; yet, strange to say, no such action was taken by them until the spring of 1877; and this, notwithstanding the injury since complained of, was all the while going on, and the miners, instead of abating their energy, were opening more claims, building new and larger ditches, employing more powerful washing apparatus, and otherwise extending and intensifying these agencies of mischief. It was, in fact, during these 15 years of inaction and seeming indifference on the part of the farmers that most of the heavy investments on account of hydraulic mining were made, the amounts so expended having aggregated them \$40,000,000 or \$50,000,000.

The North Bloomfield Company alone disbursed in this time nearly \$4,000,000 in the purchase of mining grounds and water franchises, and in the construction of ditches, tunnels, reservoirs, etc. This, too, was the period when English funds went into the business quite freely, something like a million dollars having been expended with the expectation on the part of the investors, and under an implied guarantee on our part, that the business was to go on unmolested. By reason of their slothfulness and silence these farmers, it is contended, have been guilty of such laches as should defeat their claim for relief in the manner asked for, and even deprive them of any standing in the courts. They suffered us to go on, say the miners, and waste all these years and lay out all this money, and just now when we have overcome the many obstacles incident to the business and worked it up to a paying point, they jump upon us and ask the courts to restrain us from further operations.

The money invested in what may be termed live mines, that is, such as are now making an active and generally a profitable production, amounts to between \$60,000,000 and \$70,000,000. This money, which has gone for the purchase and outfitting of mining properties, has all been expended in good faith, the miners never suspecting for a moment that their right to employ the outletting streams, after such long use and its sanction by law, would be called in question; least of all by a class of men who, during these many years had, by implication, been assenting to what they were doing.

These parties, say the miners, who are now pursuing us in the courts, are

Inconsistent as well as Unjust.

They went upon these lands informed as to the claims of the miners, and ought not now to complain if the latter resist their demands and combine to defend what they believe to be their just rights. They failed at the proper time to notify the miners and the investing public of their grievances and of their intention to seek redress through recourse to litigation. When the fatal slums first began their encroachments, these land owners neglected to throw up such slight levees as, with some little additions every year, would have served to keep this stuff in check; sitting down listless and idle until the evil had spread beyond control.

Besides, say the miners, we did not lay the foundation for the trouble complained of; this was mostly the work of our predecessors, who accomplished it in the manner already indicated. Then, too, the soil over six millions of acres of land throughout the country tributary to these rivers and their confluents are now being plowed, or otherwise stirred up, sending down immense quantities of sediment; more, perhaps, than has of late years been discharged from the hydraulic mines. Here is an agency potent for evil but of which little has been heard, though it ought to bear its just proportion of the injury done. A majority of the hydraulic companies at present operating—the most of the loose top dirt having long since been run off—are now at work on the cemented

gravel below; more than half of which consists of bowlders that never leave the washing pits at all, while a large percentage of the tailings are so coarse that they lodge before getting very far from the mines. Of material fine enough to be transported for any great distance much less is now discharged than formerly.

Moreover, the mass of the tailings at present resting in the river channels, has so spread out that the shallow current of water running over them has not force enough to carry anything but the finer silt 'down' as far as the farming lands; and this material, a great deal of which is floated into the lower hays, and even out into the ocean, is so fertile, so fine, and so small in quantity, that it can cause but little damage should some of it be left on the land.

Should another great flood occur, it would not now be likely to disrupt and carry down stream the debris lodged in the river beds, as this stuff has not only so spread out as to greatly diminish the force of the water, but it has become so impacted that even the extremest flood would hardly suffice to tear it up.

The fear that hydraulic mining will be greatly extended hereafter is not well founded. This business must always be limited by the quantity of water available for carrying it on; and as very nearly such quantity has already been appropriated and brought into use, this industry can undergo but little expansion in the future.

If the water in the rivers is to be preserved clear and uncontaminated, as many of our opponents contend that it should be, then, say the hydraulic men, there must be an end to all mining, as this cannot be the case if even vein or drift operations are suffered to go on. To establish the rule that suits may be maintained against any class of miners for rendering the water in the rivers turbid, or for depositing sediment in their channels or along their banks, would be to utterly extinguish every branch of mining, inasmuch as every branch, if continued, must necessarily contribute something towards producing these results. It avails not that the farmers disclaim any purpose of proceeding against the quartz and drift miners. Already some of the latter have been threatened with suits, and let but the above doctrine prevail, and the ruin of every class of miners would be speedy and inevitable, as any one, however small his damages, might bring suit against them.

If the rivers, during high stages of water, overflow their banks, this is no new thing, as they have always done so. When extreme floods occur, the channel of the Sacramento is able to carry but a small portion of the water brought into the valley, from three to four fifths of the whole spreading out over the tule lands, on which it deposits great quantities of sediment to their great benefit.

While the bed of the lower Sacramento has been raised to the extent of about six feet, the bars in the river have been so little shoaled that a small amount of dredging would suffice to maintain its navigation unimpaired. As regards both the Sacramento and Feather rivers, their summer navigation, instead of being injured, has been improved through the operations of the hydraulic miners, the immense quantity of water stored in the mountain reservoirs, and discharged during the dry season insuring to these streams a better stage of water than formerly.

If the hydraulic mines are closed other very extensive and important interests will be made to suffer besides those of the miners themselves. In the first place, there is being turned out by this class of mines from twelve to fifteen million dollars annually. Their product consists wholly of gold and could not well be spared just now from the circulating medium of the country, as it constitutes about one third of the entire gold crop of the United States. With us the product of gold has for some years past been falling off at a rate calculated to seriously disturb the relative value of the two royal metals, and cause much uneasiness in financial circles. 'To cut off now this prolific and reliable source of supply could not fail to increase this uneasiness, and might even precipitate a crisis in our monetary affairs.

On the prosecution of hydraulic mining large communities are almost wholly dependent for their subsistence. To prohibit the business would nearly depopulate extensive districts now filled with comfortable homes and a well-

to-do people, the country, in the absence of mining possessing no other resources that could afford these people a livelihood. And so the miners reply to their opponents, and argue the question in their own behalf.

Judge Temple's Decision.

Under the decision rendered by Judge Temple the hydraulic miners who have been stopped from working their claims by injunctions issuing from the courts, may, as soon as they have made ample provision for impounding the coarser portion of their tailings, resume work and go on as before; the court refusing to hold that they may be enjoined from working their claims because of the injury done to the water alone. While this finding was only against a single company, it establishes a principle that applies to all hydraulic operations. To the principle so enunciated, the miners do not object. They are willing to abide by the findings of Judge Temple, most of the larger companies having already proceeded to build dams for the retention of their tailings. Some of the companies, however, decline to incur this expense until the decree of Judge Temple has been passed upon by the Supreme Court, to which the case has been appealed, and before which it is still pending. Should the decision of the Court below be sustained, these parties, conforming their action to its requirements, will also go on and make provision for impounding the coarser portions of their mining slums by building dams and reservoirs for the purpose.

It is the opinion of most experts that these receptacles will so far subserve the end for which they are intended that the Courts will feel justified in allowing the parties who build them to continue gravel washing. Meantime, all the hydraulic miners have kept at work except the few companies who have been enjoined from doing so; and those, like the rest, are either awaiting the action of the higher Court, or going on and constructing retaining dams in anticipation of a favorable decision.

The Probable Outcome.

The hydraulic miners profess to see through their compliance with this new policy an end to their trials and troubles. The farmers, however, regard the plan proposed by Judge Temple with some distrust, and it is probable enough that it will, even if carried out in the most efficacious manner practicable, fail to cure the evils complained of. But it will go a good way towards that end, and prove a serviceable auxiliary to such other measures as may be devised for its more full accomplishment, for it may be taken for granted that some method will be evolved for protecting the large interests imperiled by these mining slums other than the destruction of the mines themselves. To kill a great industry because its continuance will work some considerable harm to other interests, is not the American way of doing business. To so deal with even the most perplexing problems is not suited to the genius of our people. It is rather our way to exercise our ingenuity, tax the resources of science, experiment, compromise, and even practice a little injustice, if needs be, sooner than see a pursuit, built up at such a cost, so beneficent, so well entitled to live, strangled to death by judicial process.

This, it may be assumed, will not be done. Impounding reservoirs of immense capacity will be built in the mines. The outletting streams will be dammed at all eligible points. Ditches will be constructed for conveying these slums out and distributing them over the dry foothills and the barren prairies. Great flumes will be laid down for carrying them off and depositing them on the tule marshes, where they are greatly needed. This and much more of a remedial kind having been accomplished, the farming lands and the cities will be reasonably protected, the harbors will be saved, and the rivers preserved from shoaling, and hydraulic mining will, in all probability, be suffered to go on without further interruption.

M. BUTLER JONSTONE, an English capitalist and a heavy owner in the Broadway property at Silver Star, says the *Helena, M. T., Herald*, will resume operations shortly, and will erect machinery of a costly pattern, with which to treat the ore by a new method.

TUCSON, A. T., is lighted with masts, similar to those used in Los Angeles, with the large Brush arc lights, and the Swan incandescent light will be used for domestic lighting, the storage reservoir system being used.

MECHANICAL PROGRESS.

Resharpening Files.

The old method of giving files a second life was by rescutting. So far as this was confined to files with sufficient body to sustain the second assault, it may have proved to be economical. But there are many files used which are necessarily thin, and not capable of being reduced from their thinness.

To recut a file, the file must be ground down to the "plate," the smooth surface below the "roots" of the teeth. All the teeth must be ground out, and the space below the "roots" of the teeth also, if good afterwork is expected. And then it is only the thick files with fine cuts that are of any value for recutting purposes. With a coarse file, as a bastard, or a mill file, the blows of the cutter's hammer have disturbed the relations of particles in the slab of steel so seriously that they have almost disintegrated the steel before the hardening process had made the incipient cut of the chisel noticeable to sight or subject to fracture. So it does not always "pay" to anneal, grind and recut a worn-out file.

But the useful life of the file may be perceptibly and economically prolonged by proper care. Sometimes the teeth of new files are broken off before performing useful work by "bearing on" to a file, and attempting to rasp through the foundry skin of an iron casting. Sometimes new files are clogged with soft metals. In either case the trouble has been done before the file has had its chance. The newly cut teeth of the file should be protected from abuse. The file tooth is similar to the razor edge, and has a fringe of self-supporting fibers requiring the gentlest treatment at the first. After this "wire edge" is worn off—not roughly broken off—the file teeth are ready for their daily duty. To perform this they should be kept clean. It is not alone the finishing files, used with oil as a lubricant, which get foul with a gurry of oil and file dust, but there are dry used files which have lodged between their teeth slices of wrought iron, splinters of steel, and crumbles of composition of brass, or of babbit. To remove these obstructions is one of the duties of a filer, and the proper methods for this removal ought to be a part of every filer's education or a lesson in his instruction.

For cleaning a greasy finish file there is nothing better than a burning over the forge fire, in the flame of an alcohol lamp, or of a gas blaze. The burning should be done by a gentle passage to and fro through the flame, until the grease on the file burns with a blaze. Then the blaze should be blown out and the file be carded. When cleaned, dip the file into a jar of lye and clean in pure water.

For removal of clogged particles a chisel of flattened wire is as good as anything. This is used by hand, and its mechanical effect is simply to drive out the lodged particles by ploughing process.

For resharpening of file teeth acids have been employed, and to a certain and limited extent they are valuable. For this process the file must be chemically clean. This is insured by a soluble alkali, as lye, or an immersion in benzine, or naphtha, or spirits of turpentine, then a bath in clean warm water. The cleaned file may be placed point down in a jar of acid made up of half nitric acid, half sulphuric acid, and the combined amount of water—that is, as much water as the quantity of the two acids. The file, resting too down, may remain in this solution an hour or more, according to the depth of the teeth. But a much simpler method is to wash the cleaned file with the pickle at the foundry, and when it dries off wash it again, repeating the process several times, and finally washing off with clean water or with lye water and clear water.

It is doubtful, however, that this acid method ever really sharpens the teeth of the file. It cleans the file chemically, and allows it to do its work better than when the file is clogged and dirty. The only resharpening of files is of a mechanical character, and that is a contrivance that shoots sand and water or emery and water against the file teeth, at their back, with the force of a boiler pressure of steam from 60 pounds to 80 pounds per square inch. In this contrivance, which has been in successful use for many months in some of our large establishments, from a tank holding quartz, sand and water the mixture is drawn up through flexible tubes and directed simultaneously against the upper and lower surfaces of the file by the force of the steam. The steam acts in this case exactly as it acts when employed as an injector of water into boilers—the steam force lifts the diluted sand bath and directs it, with its boiler force, against the teeth of the file as the file is passed back and forth through the converging fires of the two tubes.

The result is a great improvement in the useful life of worn-out files.—*American Inventor.*

THE GAS ENGINE.—Prof. Ayerton has shown that the internally fired gas engine has a much higher efficiency than either a steam or hot air engine. At the same time, he makes the point that the gas engine using illuminating gas as fuel occupies the same position that, a few years since, was held by the electro-motor in which zinc was used in generating electricity. The Professor grows enthusiastic over the possibilities of a lower priced gas, and says: "If it shall be possible to manufacture a cheap heat-

giving gas, small gas engines driven with such gas will not only surpass in economy steam engines of the same size, but will produce energy at a cheaper rate per horse power than the largest steam engines ever made." This gas it is already more than "possible to manufacture." The non-illuminating water gas of the Lowe process is the very desideratum the English professor is looking for. He can find it right here. The question is not one of its coming, but how long will it take our manufacturers, architects, builders, and power users generally, to recognize and realize this coming?—*Water Gas Journal.*

STEEL WATER PIPES. The Chambray Co. makes pipes of steel plate for conveying water under high pressure. The steel plates are coated with lead on both sides by immersion or otherwise, then rolled to form, riveted, and soldered the whole length, and covered with pitch. The first cost of the steel is not much greater than that of iron, and the steel pipes possess considerable advantages over those of iron. The lead coating is superior on account of the fineness of grain in the steel; the resistance to tensile strain and internal pressure is 50 to 60 times, and the resistance to deformation longitudinally from 30 to 40 times greater, while the superior elasticity of the steel plate permits of the pipes receiving tolerably hard knocks without being permanently deformed. For equal thickness the steel tubes stand twice the internal pressure of the iron, and being both light and strong, they are admirably adapted for laying down temporarily and taking up again.—*Iron.*

THE CORROSION OF IRON AND STEEL.—At a recent meeting of the Paris Academy of Sciences, a paper was read describing some researches by M. Gruner, on the relative corrosion of cast iron, steel, and soft iron. Various plates, suspended in a frame by their four corners, were immersed simultaneously in water acidulated with 0.5% of sulphuric acid, or sea water, or were simply exposed in moist air of a terrace foundry. In moist air, chrome steels were corroded most rapidly, and tungsten steel less than carbon steel. Cast iron, even when high in manganese, is oxidized less than steel and soft iron, and white forge pig less than gray foundry iron. Sea water, on the other hand, attacks cast iron more than steel, and with special energy white iron. Tempered steel is less attacked than the same steel annealed; soft steel less than steel high in manganese or chrome steel, etc. Acidulated water, like sea water, dissolves gray pig iron more rapidly than steel, but not white iron; the gray, impure pig iron is most strongly attacked. These results agree with the complete experiments on the subject by Mallet, in 1843.

MONSTER STEAM WHISTLES.—A firm in Bridgeport, Conn., has recently completed a steam whistle for a Canadian saw mill, the bell of which is 20 inches in diameter, a quarter of an inch thick and 27 inches long, and is placed five inches from the cup which delivers the steam. The valve is of the ordinary spring pattern, and is four inches in diameter. The weight of whistle and valve is 406 pounds, and the cost of the monster is \$500. The mill for the protection of which it has been made, has been several times burnt down, and the object, therefore, of the whistle is to arouse the surrounding country in case of a recurrence of the catastrophe, and also to carry signals to wood-choppers in the neighboring forests. There is another big whistle at New Brunswick, in New Jersey, with a deep bass hum which serves as the clock regulator for farmers and others within a radius of 20 miles of the town. There is also a whistle at Sandy Hook 15 inches in diameter, while many of the ocean and sound steamers have whistles from 8 inches to 10 inches, which can be heard from 10 to 20 miles.

A NEW COPPER-ZINC ALLOY.—*Engineering* says that Mr. Alexander Dick has succeeded in producing a new copper-zinc alloy which exhibits characteristics as essentially superior to brass as those of bronze are to gun metal. The advantages claimed for the new alloy, which has been named "delta metal," are great strength and toughness, and a capacity for being rolled, forged, and drawn. It can be made as hard as mild steel, and when melted is very liquid, producing sound castings of close fine grain. The color can be varied from that of yellow brass to rich gun metal; the surface takes a fine polish, and when exposed to the air tarnishes less than brass. The latter characteristics will meet with ready appreciation for cabinet work, harness fitting, etc. The metal when cast in sand has a breaking strain of 21 to 22 tons per square inch; when rolled or forged hot into rods, the breaking strain is 43 tons per square inch; and when drawn into wire of 22 B. W. G., of 67 tons per square inch.

TO PROTECT IRON AND STEEL FROM RUST.—Prof F. Grace Calvert, of England, has discovered that the carbonates of potash and soda possess the same property of protecting iron and steel from rust as do those alkalies in a caustic state. If an iron blade is half immersed in a solution of either of the above carbonates, it exerts so protective an action that that portion of the iron which is exposed to the influence of the damp atmospheric air does not oxidize, even after a period of two years. Similar results have been obtained with sea water to which have been added the carbonates of potash or soda. The applications of this fact are numerous and important.

SCIENTIFIC PROGRESS.

The Movement of Water in Plants.

The *American Journal of Science* gives some interesting particulars in regard to some recent observations by N. Julien Vesque in regard to the movement of water in plants. That gentleman has devised a very simple method of demonstrating the transfer of water in the stems of plants, which promises to have a wide application. The stem is cut obliquely during immersion in water, and the thin part of the severed stem is placed in the field of the microscope, of coarse completely wet on the cut surface. After the cover-glass is adjusted and the stem is securely fastened, so that it cannot be easily disturbed by subsequent treatment, a very little freshly precipitated calcium oxalate or other finely divided substance, is introduced under the cover. If the leaves have not been removed from the stem, a rapid current is at once observed to flow towards the cut surface. The insoluble salt collects at the open mouths of the vessels, often passing into the capillary tubes after a temporary arrest, and the same phenomenon is repeated several times as the minute plugs are formed and then sucked in.

With low powers of the microscope it is possible to use a second slip, instead of the thin cover, and then the simple apparatus can be held more firmly in its place. In any case it is possible to measure the rapidity of the current by means of a micrometric eye-piece; and several such rates are given.

When the stem is quickly stripped of its leaves the current is stopped at once. But when, on the other hand, a leaf or a part of the stem is pinched, there is immediately a backward flow of water.

It is well known that two conflicting views have been held by physiologists as to the channel by which the upward movement in wood takes place. Some think that the transfer is solely by imbibition, and that no free water is carried from cavity to cavity of the wood element, or rather, that no free water exists in the cavities. Others have held that free water was carried from one wood element to another, and that the walls themselves play only a subordinate role. To these opposed views may be added a third, which appears to be a compromise; namely, that water in a free state actually exists as a thin lining on the cell wall. The chief advocate of the latter view has, however, abandoned it in favor of the imbibition theory. A recent publication by Eifving details the results of experiments which considerably strengthen the "cavity" theory. Now just at this point come observations of Vesque, in a continuation of the paper regarding the method of direct demonstration, which go far towards showing that here, as was long ago suspected, the truth is to be found between the extremes. These experiments, which need to be carefully repeated, indicate that under certain circumstances the transfer of water takes place by means of the cavities themselves, but that in all cases they may serve the part of reservoirs.

Moreover, the caliber and length of the vessels regulate the rate of transpiration; resistance to the movement of the water following the law of Poiseuille, so that the resistance is inversely proportional to the fourth power of the diameter, and directly proportional to their length. Climbing plants have larger vessels than low-growing plants. The quantity of water which can pass through a vessel in a given time bears a certain relation, varying for each species with the water which it contains. M. Vesque expressed the opinion that the study of the anatomy of plants will open the way to a more national culture than any which now prevails.

Underground Temperature.

The British Association committee on underground temperature, in their last report, adopted 64 feet per degree rise in temperature, or 0.01566 of a degree per foot depth. To obtain an approximation to the rate at which heat escapes annually from the earth, they reduce the above rate of increase, .01566, to Centigrade degrees per centimeter of depth. For this purpose, we must multiply by .0182, giving .000285. To calculate the rate of escape of heat, this must be multiplied by the conductivity. Prof. Herschel, in conjunction with a committee of the British Association, has made a very extensive and valuable series of direct measurements of the conductivities of a great variety of rocks, and has given additional certainty to his results by selecting as two of the subjects of his experiments the Calton Hill Trap and Craigleith sandstone, to which Sir William Thompson's determinations apply. From combining Prof. Herschel's determinations with those of Sir William Thompson, .0058 is adopted as the mean conductivity of the outer crust of the earth, which, being multiplied by the mean rate of increase, .000285, gives the flow of heat in a second across a square centimeter. Multiplying by the number of seconds in a year, which is approximately 31½ millions, we have 1,633x31½x10¹¹=41.4. This, then, is the British Association committee's estimate of the average number of gramme degrees of heat that escapes annually through each square centimeter of a horizontal section of the earth's substance.—*Van Nostrand's Engineering.*

The Red Spot on Jupiter.

At the first regular meeting of the American Astronomical Society, held March 3d, the topic for discussion was the "Physical Changes in Jupiter." A paper on the "Red Spot on Jupiter" was expected from Mr. S. V. White, the President of the society, and there was considerable disappointment over his inability to be present.

The remarks of the members were confined to the recent changes in Jupiter. Messrs. Parkhurst and Serviss described their observations of the great red spot which made its appearance on Jupiter's disk in the summer of 1878, and which within a few weeks has almost entirely disappeared. Others took part in the discussion.

The general opinion expressed was that Jupiter is a world which is yet in a very early stage of its geological history, and that in the great red spot, and in some other remarkable spots which have made their appearance upon its surface, evidences are seen that the planet either has already a solid or liquid surface, or that the formation of such a surface has begun. Several theories to account for the great red spot, which was upward of 30,000 miles long by 6,000 or 8,000 miles wide, were suggested.

One theory was that some volcanic action may have been taken place, which threw up into the atmosphere a mass of smoke and erupted materials which formed the red spot. Another theory was that the crust of the planet where the spot appeared may have been exceptionally heated, so that the atmosphere above it was kept free from clouds. A third theory regarded the red spot as possibly a solidified mass thrust up through its gaseous and liquid surroundings, and forming, perhaps, the nucleus of one of the future continents of the giant planet. The difference between rate of rotation of the red spot and the white spot in the southern belt was referred to. The red spot overtakes the white spot once in 34 days.—*Scientific American.*

USE OF THE MICROSCOPE IN BREWING.—Not only is an impoverished yeast unable to develop an active and healthy fermentation, but being itself so weak it is less able to battle against the different disease ferments, which always become more active as the yeast itself loses its vitality. The persistent use of the microscope is, says the *Brewer's Guardian*, the only means by which the necessity for a change of yeast can be recognized, and, therefore, the yeast from each brewing ought to be examined from day to day; as soon as the cells are observed to lose their rotundity, to elongate and to acquire something of the shape of the figure eight, as it is a sure sign that some deterioration is taking place, and when the cells become filled with granular matter it is certainly time to make a change, for the yeast must then be seriously weakened. Simultaneous with these alterations in the appearance of the yeast cells the careful observer will be sure to find that numerous other organisms, such as bacteria, lactic and other diseased ferments, begin to make their appearance, and if the use of such a yeast is persisted in, the resulting beers cannot long remain sound and with a proper and normal flavor. Frequent and unnecessary changes of yeast are to be deprecated, but it is far more serious to continue to use a yeast when once degeneration and deterioration have set in.

THE EFFECTS OF OIL UPON WAVES.—In reply to an objection of Admiral Bourgeois that the actual effect of oil upon waves should be fully tested before it is submitted to theoretical analysis, M. G. Vander Mensbrugge replies, that he has shown from incontestable facts that the wind produces upon the superficial layer of the sea, a horizontal motion of translation, which being sufficiently prolonged can communicate to the deeper layers, and can propagate to a great distance, very decided undulations. He has confined himself to a discussion of two cases; in the first, where the calm sea is covered with a thin layer of oil and is then submitted to the action of the wind; in the second, where the waves break. In the first case the formation of great waves is rendered impossible by the presence of the layer of oil. In the second, a simple calculation shows that the layer of oil exerts a great resistance at the base of the breaker, and thus compels it to extend itself and to subside very rapidly without producing severe wave shocks.—*Comptes Rendus.*

WATER TO BE CARRIED AS GAS.—M. Pasteur, a nephew of the celebrated chemist of that name, has recently adapted an old discovery to great practical use. It is a well-known fact that the crossing of the great African desert is accomplished by means of caravans composed of camels, horses, etc., the water for which has to be transported on the back of the consumer. This lessens to a great degree their freight capacity. M. Pasteur has established suitable works at the numerous termini of the routes for separating the water into oxygen and hydrogen. As the latter is 16 times lighter than the former, and is the gas used in balloons, it carries the oxygen and a considerable part of the camel, besides furnishing light on dark nights. He unites the gases by the simple means of explosion when desired for use. The French Government has created M. Pasteur a Commander of the Legion of Honor for his great adaptation.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned

HOOSIER MINE.—The mine is located on the rugged country on the Calaveras river about three miles above Jesus Maria. A ten-stamp mill has been erected with useful appliances, including feeders and rock-breakers. But ten stamps have been put up for the present but the frame work was constructed so as to permit the addition of ten stamps more. The mill is run by a hurdy-gurdy water wheel, the necessary pressure being easily obtained by a ditch tapping the Calaveras river a comparatively short distance above, and supplying free water for running and all other mill purposes. The claim comprises three locations, the Mary Lory, the Way Ground and the Hoosier, all of which is included in the Hoosier Consolidated. Notwithstanding the nearest point from which ore has been taken is several hundred feet up the steep mountain side from the mill, the admirable arrangement for economic prospecting purposes permits comparatively easy conveyance of the ore to the mill. Four tunnels have been run at intervals along the course of the lead besides prospecting shafts, in all of which was found good rock and the indications of the existence of a true fissure vein. A tramway 113 rods in length with a grade of one foot to the rod was constructed, reaching from the Hoosier tunnel to a point above the mill, with which it is connected by another tramway 300 ft in length directly down the hillside where the steeper slopes at an angle of about 45°. By means of a wire cable working upon pulleys at the upper end of the track two cars are run upon it, the descending loaded car drawing up the empty one, and by a contrivance called a "cradle," at the entrance to the mill, the car is made to dump itself, the car remaining on the upper tramway regulating the speed of the descending car by means of an effective brake. By the time the loaded car has reached the mill, the ascending car is in place ready to be filled. The first run of 75 tons of the ore from the old dumps exceeded the estimate made, and yielded 37 per cent. The indications are that the present run will equal if not exceed that figure, and as the cost of milling the

SOUTHERN UTAH is reported as having but little snow in the mountains, while the valleys are very dry.

rock, as we are informed by Mr. Mayon, does not exceed \$2.50 per ton, it is plain the investment is not a bad one.

EL DORADO.

GREENWOOD.—*Georgetown Gazette*, March 24: At Zentgraf's we see the new stamp quartz mill, a plain free gold one, with a 30 feet diameter overshot water wheel, the water supplied from the Cal. W. & M. Co.'s ditch, being conveyed by flume across the road from a safe and compact reservoir placed at a sufficient height to be available in case of fire in the mill; everything around is in perfect order and betokens prosperity. Mr. Zentgraf's son and nephew run the mill on alternate shifts, night and day. We visited the mine where we found the miners stopping, the ledge varying from two to seven feet in thickness, all good looking ore. Mr. Zentgraf, whose cheerful smiles, as he proudly shows you his express receipts for bullion, convinces you that he is satisfied with his investment, and, indeed, he should be, for he says that since the mill started to run he has tried ore from various parts of his large mine, and always with satisfactory results. No rich pockets—no splendid specimens; but good mill ore of a grade sufficient for profitable working. This summer Mr. Zentgraf proposes to add another battery to the mill, run a tunnel from the mill to the ledge, from which he will be able to dump his quartz on the floor in the feeding room, at a saving of a dollar a ton over the present method of hauling and dumping, and continue sinking the main shaft from which to open and fully develop the mine. Mr. Zentgraf carefully and thoroughly prospected this mine till he felt justified in placing thereon the present mill, the results from which fully warrant his increasing his power of reducing ore, and he will further pay attention to the saving and working of the sulphurets which will certainly increase in quantity as greater depth is attained.

MR. PARKHURST, who was down from Volcano-ville, Wednesday, informs us that R. G. Hart expects to start up his 10-stamp mill on the Josephine mine on Friday of this week. Mr. Hart was one of the most thorough quartz mine operators of Nevada county, and that is saying a good deal, for Nevada county has a world-wide reputation for milling quartz. Mr. Hart has displayed much energy in developing and placing this mine in good working condition. Everything about the mine and works is constructed with a view to permanency. The ledge has been thoroughly opened up on the second and third levels, by tunnels run in on the ledge from the mountain side. It is below the mouth of this lower tunnel where the new works are built. The mill will be run by water power. Parties who have recently visited the mine are much elated with the richness and magnitude of the ore, declaring that it is the best mine in the county, and that the new works are a model of perfection. Mr. Hart is one of those cautious, practical mining men who operates a mine on its true merits. Such men are an honor to the State. They lift up our mining resources, by careful and intelligent investments, while schemers and swindlers speculate off our eastern brethren by handling mines which a man like Hart would not be guilty of recommending to any one. Such proceedings have been carried on in this county, and our mining interests have received a terrible back-set in consequence.

CONTRACT LET.—Last Saturday J. E. Lyon let a contract for a 200 foot extension of the Lyon tunnel, through the Mount Hope to the Flagstaff mine. This tunnel will tap the ledge in the Flagstaff at a depth of 200 feet, which will be worked through the tunnel.

GOOD NEWS.—Supt. W. A. Jones, of the Placer-ville Gold Quartz mine, returned from San Francisco last Tuesday, after an absence of two or three weeks, and assures us that the P. G. Q. will start up again within a few days, certainly within ten days, and that operations will be steadily prosecuted on the accustomed scale. This will be hailed as good news in mining circles.

THE RIP VAN WINKLE.—This mine, owned by A. A. Gignae and M. McGonagle, is located about 400 feet west of the Mount Hope mine, of which J. E. Lyon is Superintendent. After running a tunnel into the Rip Van Winkle 130 feet they struck a two inch seam of rich quartz, which, after following it 10 feet, has widened to 12 inches of ore that averages from \$15 to \$20 per ton.

MONO.

MAY LUNY MINE.—*Bodie Free Press*, March 24: K. T. Pierce, of Sundy, who has been below during the winter, is again among us. Work in the May Luny mine will be resumed at once, with about the same force as last year. The erection of a new mill will not be commenced at present.

MARIPOSA.

UNION.—*Cor. Mariposa Gazette*, March 24: While here, I took a short run over to Sweetwater, where I found my old friend Rice in the face of his tunnel, on the Union mine, which, now is in about 160 ft., with very favorable indications of striking the vein in the near future. The croppings certainly show some fine specimens of rich ore. Should this ore continue to the tunnel level, the Union will assuredly prove a rich and valuable mine. Adjoining the Union is the Mountain-view, which, also has flattering prospect. While here, I went over to the old Harbert mine now owned by Messrs. Grove and Ellingham, who have done considerable prospecting since the property came into their hands. The main shaft has attained a depth of 90 ft., with a good vein of good mill ore running the whole distance. At this point they encountered water, which necessitated the erection of hoisting and pumping machinery, which is now in course of erection and will be in running order, in 15 or 25 days. We returned to the Mountain-view House. Leaving this place on the following morning, we cantered to Snow creek, thence to the old Buckingham mine, now called the Vanderbilt. Recent developments have shown that this mine is destined to be one of the great bullion producers of this coast. Its vein crops out very prominently for a distance of a mile in length, with a width of 25 ft. They are now driving on the vein from the south end of the mine, and are in 30 ft., showing a regular, well defined vein the whole distance, of an average width of 8 ft., showing free gold and sulphurets of a high grade. Average samples taken from this point show an assay value of \$15 per ton, in gold and silver, and the concentrations, \$900.

PLACER.

THE GOLD BLOSSOM.—*Placer Herald*, March 24: At the Gold Blossom quartz mine, a short distance below Ophir, the mill is running steadily, and everything is turning out to the entire satisfaction of those interested. This mine was purchased last fall, and the new owners have put up new hoisting works, a fine new mill with all the modern appliances for saving gold, a large patent furnace for roasting the sulphureted ores, and other appurtenances essential to the thorough equipment of a mine. The clean-up for February was highly satisfactory, and the present run bids fair to be even better. They are down now about 200 feet at which depth the size of the ledge is undiminished, and the ore shows no deterioration in quality. The success of this enterprise will have a good result in increasing confidence in the district and promoting the development of our numerous quartz leads.

A MAMMOTH LEDGE.—Wm. Werry, one of Placer's enterprising mining men, claims now to have not only the "biggest thing on ice," not only the biggest thing in Placer county, but the biggest thing in the way of a mine in California. It is a quartz lode, located on the side of the American River Hill, about four miles south of Colfax. It is a well defined fissure vein, at least 50 feet thick, and numerous prospects from different parts of the ledge show the rock to average from \$6 to \$12 per ton. A mill test of 180 pounds yielded \$1.12.

SAN BERNARDINO.

CALICO MINING NOTES.—*Calico Print*, March 24: Work is still progressing in the new shaft in the Geneva. They are taking out some good ore; 150 sacks have been taken to the Pioneer mill at Hawley's station. Work is progressing on the Tiger, Great Eastern and Rocky Point, owned by Dr. Turpin and others. Ore is being taken out daily from the Sue, Humbug, Kearsarge, Thunder, and a large quantity was brought from each of them the other day by S. P. Holden, of San Francisco. It is reported that the Pioneer mill, recently purchased by the Silver Odessa Company, is soon to be enlarged to a 10-stamp mill. It is busily at work on good ore. It is reported that a rich strike has been made about a mile west of the Total Wreck. The other day 30 sacks of first-class ore was shipped from the Little V to S. P. Holden, ore buyer, of San Francisco. This mine is now owned by Wm. Raymond, J. H. Kane and T. H. Eccles. It is a beautiful little mine and exceedingly rich. The invincible sent 25 sacks of fine ore to S. P. Holden the other day. The Comet, situated between the Little V and the Invincible is now being worked by Tom McFarlan, and the rock taken out looks well. Two men are chloriding on the Veto with good results. The average assays of the Thunder is \$390.

TOTAL WRECK.—The owners of this claim are energetically at work developing it, and they feel highly elated over the results of their labors. The last reports from this claim were decidedly flattering. The ledge, which at first appeared to be small, has proven to be of considerable size. Sixteen feet from the surface it shows splendid walls, and is getting wider and more solid as they go down. They are now sinking a shaft instead of an incline. The character of the ore improves as they descend. The ledge was examined by Mr. Maddox, a mineralogist and mining expert, and pronounced to be a good one. The returns of some specimens, which were sent to Los Angeles, shows that it goes well up in gold. The assayer said that the ore came from a natural formation. They are making room for a windlass, and will commence to sack ore soon.

SHASTA.

WHISKYTOWN.—*Shasta Courier*, March 24: The Mad Ox mine owners will soon have on the ground machinery for a steam mill of good capacity. When in operation they expect to crush 500 tons of quartz a month. They have recently added several to their force of workmen and I understand purpose to put on about 20 more. On Mad Mule they are working a force of half a dozen, cutting through to strike a seam. We drop a tear over gulch miners and arastars until it rains.

TRINITY.

QUARTZ EXCITEMENT.—*Trinity Journal*, March 24: Some very rich specimens of quartz were brought to town this week by Mr. Chris. Meckel, of North Fork, from a ledge recently located by John Day, Jas. Moore and Will Day on the head of the East Fork, about seven miles above the town of North Fork. From a piece of this rock, weighing four and one half ounces, 18 cents in gold was taken by simply crushing it in a mortar and panning out. This is at the rate of \$1,280 per ton, and the specimen was not regarded as more than a fair sample. The lode has been traced a distance of 3,000 feet, running nearly east and west; it lies flat, or horizontal, and is from one and a half to two feet thick. How far it may extend into the hill is not known, but if what is in sight averages anything like that sent to town the boys have an immense thing in that alone. This find has already stimulated some to prospecting and several parties have already set out. The whole country in the neighborhood of this discovery is covered with quartz, and lodes of all sizes are plenty. The gulches thereabouts paid largely in early days in quartz gold, and every indication points to the probability of numerous valuable discoveries.

NEW RIVER QUARTZ.—Assessor Marshall returned to town, Wednesday, after a couple of weeks official trip to Lower Trinity and New River. He tells us that placer mining is generally dull, owing to the dry season, but that on New River some good quartz prospects have been found and that the work of developing ledges will be prosecuted with vigor and every prospect of success the coming summer.

Nevada.

WASHOE DISTRICT.

UNION CON.—*Enterprise*, March 24: Good progress is making in the joint Sierra Nevada east crosscut on the 2900 level, but during the week there has been no change of material worthy of note.

OPHIR.—The usual repairs are being made, and ore is again being extracted from the croppings.

GOULD & CURRY.—The west crosscut is being advanced toward the west wall in vein material of a promising appearance. The crosscut is now out almost 700 feet. The diamond drill was put into the face this week, and showed considerable very hot water ahead.

YELLOW JACKET.—The yield of ore from the old levels at the Winters' shaft has been increased to 75

tons per day. A good deal of prospecting is being done at several points.

SIERRA NEVADA.—Good headway is being made in the joint Union Con. east crosscut on the 2900 level. The face is in vein material which exhibits no features worthy of special note.

CON. VIRGINIA. The southeast drift on the 2500 level making very fair progress. It is very hard at the face, but there is no increase of water.

SAVAGE.—The joint Hale & Norcross north lateral drift on the 2600 level is being rapidly advanced, and is cutting frequent feeders of metal-bearing quartz.

MEXICAN. The joint Union Con. east crosscut is in vein material, showing occasional seams of quartz.

HALE & NORCROSS.—The north drift on the 2600 level, joint with the Savage, is passing through vein material that shows frequent feeders and bunches of quartz that give promising assays.

COLUMBUS DISTRICT.

NORTHERN HILL.—*Candelaria True Fissure*, March 24: The east drift from the bottom of the main winze, from the fifth shaft level, has been extended 12 feet during the week. Its total length is 34 feet. A bunch of fine sulphurets was developed in crosscut No. 2, on the same level, in the early part of the week, but did not prove as extensive as anticipated, the face of the crosscut having passed entirely through and out of it. The fourth shaft level is producing as usual, the ore continuing of good quality. There is an improvement on the second intermediate shaft level, both in the length and width of the ore in the stope. Mill No. 1 was started on Mount Diablo ore, on Monday morning, and it is working on half time. The bullion shipments amounted to \$15,204.71 for the week ending March 22, and aggregates \$39,332.05 on March account to the same date.

MOUNT DIABLO.—The stope from the raise, nearly north of the shaft on the second level, is yielding considerable 70 ore. The west stope from the Calison winze shows 18 inches of 50 ore. A small amount of 75 ore is being extracted near the shaft on the first level.

Arizona.

MOHAVE COUNTY NOTES.—*Alta Arizona*, March 24: Dr. Brown is pumping the water out of the Keystone mine, and will start work on that splendid property at an early day. O. Groom has been sinking on the Illinois mine, at Chloride. He has about 12 inches of fine looking sulphure ore in the bottom of the shaft. The drift which Welton & Grounds have been running on the Juno, is in 70 feet, and there is a nice streak of galena ore in the face. It carries over \$400 in silver and gold. Henry Ewing and Robert Meara have been sinking on the Tuckahoe mine, at Chloride. They have from six to eight inches of sulphure ore, that carries ruby and silver glance. W. H. Bennett, well known in Colorado, New Mexico and Arizona, has recently come into possession of some fine prospects in this mining district. Isaac Conkey and William Raywood are taking out some fine sulphure and horn silver ore from the Mountain Grove. E. C. Sherman will start to work with them next week. We were shown some ore from there that is very rich. They are going to run a tunnel in on the ledge, and go to taking out ore. H. B. Cox & Co., and W. H. Davis, have located in Music Mountain, near the Silent mine, what is called the Fairview mine. We have seen quite a number of samples taken from this new find, all of which had an abundance of free gold, visible to the naked eye. The Fairview is a ledge 3½ feet thick, and free gold has been found in the croppings for a distance of over 1,000 feet. It assays \$85.27 in gold, and \$9.43 in silver.

BRADSHAW MOUNTAINS.—In a recent conversation with N. C. Sheekles, of Bradshaw mountains, we learned the following: Brittingham, Hayden & Bond, owners of the old Jinks claim, on the Lorena mine, are putting up a whim. They have about \$30,000 worth of ore on the dump and a great deal more in the mine. Their ore is certain to pay \$100 per ton. E. S. Junior has several fine claims in Bradshaw mountain, the best of which is thought to be his Cougar claim; out of it he has taken very rich rock. The mine is large. Mr. Campbell keeps on running his antrax on ore, from the Ore Bonita mine. In Bradshaw Basin, O. F. Place is developing the Buckeye and other mines. Mr. Sheekles tells us that Mr. Place's prospects are very good. He is a good mine manager. John Lake has driven a tunnel 200 ft on one of his ledges. South of the Bradshaws, in the Silver mountain country, prospectors recently struck a large vein which is said to be very rich. The Belle mine, in Big Bug district, must be a "masher," judging by the way in which it impresses miners, who describe it as being the most perfect specimen of a true fissure vein ever seen by them. Ore from it is all the time being taken to the Howell smelting works, some three miles distant, on Lynx creek.

SMELTERS.—Thinking miners now believe that smelting furnaces will solve the mining problem in our section. Most of our ores submit to the process very readily and it is about the only rational process to apply to them. This being the case, we hail with pleasure the era of smelters; which are now coming in. In fact Howell & Co., have already ordered two more smelters for their Lynx creek works.

PLACERS.—The winter just passed has not been a good one for placer miners. The clouds gave us but little snow, water has been scarce and but little placer gold has been taken out. Some of our readers may not regard this as much of a drawback, believing as they do, that the placer mines of this section are about "played." We beg leave to differ with them. The placer diggings of this section are, as yet, almost untouched. True, creek bars and beds, ravines, etc., have been more or less rifled of gold; but the heavy gravel beds still remain, and in winters such as we have had, when the country was soaked with water, they could be worked with great profit. We no longer expect to pick up pieces of gold from bare bed rock. The time for that pleasant and profitable occupation has gone by, but we do expect to get good pay out of the gravel deposits. There are miners who believe that the Senator mine, Hassayampa district, should not much longer be allowed to remain idle. Its ores could be packed at little cost, to the Howell smelting works. When milled the ore paid, and tailings from the mill also paid, for slow and expensive treatment.

MINERS.—Not capitalists—are opening some ledges in Groom creek district, which, they say, promises well.

New Mexico.

TRINIS.—*Southwest Sentinel*, March 21: John Kirk and three Mexicans are panning gold with an ordinary rocker, in a gulch south of Pinos Altos, at a profit, it is said, of \$20 to \$40 per day.

SAN PEDRO C. M. Co. have shipped their first car load of refined copper. All the shipments heretofore were in the shape of matte.

CAPT. PENROSE has made a strike of silver discovering several hundred ounces to the ton on the surface, about five miles north of the city in the Pinos Altos district.

Montana.

THE MOULTON.—*Inter-Mountain*, March 22: Mr. Pat Clark, Superintendent of the Moulton, was on the street this morning, feeling particularly good over the recent strike on that property. The new ore body was discovered on the south vein, at a point about midway between the end lines of the claim and 380 feet west of the main shaft. The shaft is now 200 feet deep, and the vein is from four to six feet wide, most of it pay ore. Ten tons of ore, which mills about \$700 a ton, are being extracted daily. The strike is increasing in width and the bottom of the shaft is now all in ore. In the main workings operations are progressing as usual and the production of 40 tons of ore per diem is regularly maintained.

STRIKE IN A PROSPECT.—The Butcher brothers have made a rich strike in a prospect known as the Bonanza, located southwest of the city. They started a new shaft a few days ago, and now, at a depth of 10 feet, have a handsome vein of ore two feet wide, assaying high into the hundreds.

SUCCESSFUL RUN ON ANACONDA ORE.—Although the Anaconda is one of the greatest copper mines on the continent, it is also a steady producer of silver ore, and for the past eight months has regularly supplied the 15-stamp Dexter mill with free-milling ore. The supply is taken principally from the 100 and 200 levels, below which the ore carries an increasing percentage of copper until on the fourth, fifth and sixth levels the ore is almost exclusively copper bearing for the full width of the immense ledge. The Dexter mill was thoroughly refitted last fall, and under the supervision of Mr. Julian Smith, has been running continuously ever since. The amount of ore worked daily is about 27 tons, which is crushed wet, and a force of 19 men is employed to run the mill. The assay value of the ore, which is free, averages about \$30, though above the copper levels there are thousands of tons of high-grade silver-copper ore, which is rich enough to ship, and which cannot be worked by the free-milling process.

Utah.

STAR DISTRICT.—*Cor. Salt Lake Tribune*, March 24: A fine body of ore has been struck in the Kanarrab mine in South Camp, at a depth of 250 ft. The ore body is large and continuous. It will assay about 50 ounces silver, and 45% lead per ton. Work still continues on the Mammoth and St. Mary mines with good results, in fact, all the mining claims that have been worked upon the past winter are looking better than ever before, and greater depth is attained, which proves that the ore bodies lay deep. Some of the claims have reached a depth of 300 ft with ore in the bottom. This district is not troubled with water, as the mines so far are dry and are likely to remain so for 1,000 ft at least. At North Camp, work has been started upon the Osceola, and some nice ore is being taken out. Also on the Dykes and Morehouse mines. The Lake Superior mine, now being worked by J. H. Lighthall and Forgie Brothers, is looking splendid, and a large body of copper ore, containing gold and silver, is being opened up.

BRADSHAW DISTRICT.—The Cave mine has stopped the shipment of ores to Frisco. Rumor has it the company contemplate the reduction of their own ore at Milford, which is 16 miles nearer the mine, at an early date. There will be money made if they do. The Horn Silver Works should have been built at Milford or some point in the valley, as the situation and facilities are here for them. Work in the Horn Silver is resumed again. The cave was expected and prepared for some time ago, but they did not expect it to go so deep as it is now. It will be all the safer to work in the future. By the cave they have saved great expense in timbering, and it was most all ore that came down. The O. K. copper mine in Beaver Lake district, is looking well and a whim is being constructed.

LINCOLN DISTRICT.—This camp is looking up again. The Frisco M. & S. Co. have become interested in it of late. Work still progresses on the Lone Brother and other claims, with favorable results.

Oregon.

NOTES.—Placer mining never was as complete a failure as this season. Considerable prospecting is going on in Jackson and Josephine counties. R. Cook of Steamboat was in town this week. His tunnel is over 250 ft. in length. A mining firm, composed of a colored man and a half-breed Chinaman found a nugget of gold, weighing nearly an ounce, on Jackson creek, a few days ago. A quantity of quartz from the Barkdel ledge in Blackwell district has been sent to Col. Wallace at Portland for assay. Several residents of this county are interested in the ledge. C. W. Kahler has made application for a patent to some ground in Big Applegate mining district. Lagg & McDonnell has also applied for a patent to ground in Jackson district. C. W. Barkdel of Blackwell, who was in town Tuesday, informed us that Welch & Co. have a force of eight men at work on the old Blackwell ledge, which they propose to thoroughly prospect. Wm. Griffin, who has a quartz ledge in Galice creek district, has sunk down on it to a depth of 30 ft., and is so well pleased with the prospects that he proposes investing in a Salmon quartz mill. He has about 100 tons of ore on the dump. Geo. Simmons, James Hansen and others are about inaugurating an enterprise that promises to be one of the most extensive ever attempted in Oregon. They propose bringing the waters of Illinois river to Mr. Simmons' ranch and upon very deep banks of gravel, which will require one or two tunnels and an immense ditch. Although it will take a large amount of capital to accomplish this, that ample remuneration is in store for them seems to be assured. The ground will be thoroughly prospected soon.

Official Villainy.

However much we may cheer our hearts and fortify our convictions with the amiable optimism, that everything in nature is ordered for the best, and that in the struggle of life the fittest wins, and that the fittest is always the best and ought to win, we must still confess that our public morality is shamefully low. Compared with what man once was, it may be tolerated, but with what his condition is, in the light of our present civilization, it is simply disgraceful. The fact that there is one eastern city that owes a debt of \$120,000,000, of which it is safe to say that at least one half has been stolen by its municipal officers, may be regarded as a specimen page from a large history. Over our national politics, Congressional and State legislation, over public contracts, the handling of public funds, and all fiduciary interests, there hangs a dark cloud of suspicion. So prevalent has official villainy become, that some one made the remark the other day, "If you see a man running across a field, arrest him on the spot, for the chances are that he is a defaulter, or has stolen something."

And this malfaisance and corruption in office is not traceable to the domination of any set of political ideas; for human nature is all cut off the same piece, all blood comes from one puddle, and the average man, whatever may be his political affiliations, will, under the same pressure of circumstances, do the same thing.

One painful fact, explanatory of this state of things, is the almost universal apathy of the masses to the moral character of their public functionaries; indeed, it has passed into a sort of sneaking proverb, that men under congressional or legislative formalities, in caucuses, handling the ropes of an election or dispensing public patronage, may do for themselves, their friends, their party, what, in common business relations and social interchanges, would be denounced as indecent and dishonorable. And what is the consequence? Whisky rings, port trader frauds, star route thieves; all sorts of thieves, torts and laches in office.

The people of Tennessee deliberately vote to reduce their taxes by repudiating the State debt. Is it strange their State Treasurer was tempted to steal the public funds? It has become a recognized rule, among all successful aspirants for office, that the political hacks, the whippers-in, the blowers and strikers must have their reward. Is it strange we so frequently hear of mismanagement and defalcation? It is the way such plausible villains as Moro P. Kay and John S. Gray usually get into official positions. We can expect to see an improvement in political morality only so far as the mass of the people rise above all party feeling, all traditional prejudice, all local and selfish interests, and shake themselves free of all cliques, rings and drill clubs, and join in a generous rivalry to see which side or party can excel in nominating the best men for office, men with the finest brain and culture, and well-known substantial habits of honor and integrity.

Another cause of this laxity in political morality comes from the neglect of courts and juries to rigidly apply the law, and the too great leniency of executives in exercising the pardoning power, especially if the criminal has great political or social influence. The State cannot wait for religion or culture to make men good and honest, for the beautiful results of religion and culture ripen slowly, and the State has no time to lose. Rome did not wait for Cataline to get religion. She banished him. Washington did not wait for England to learn justice toward the colonies. He gave battle at every sunrise. Lincoln did not wait for the evolving forces to soften the heart of the slave master. He issued his proclamation. Law is the first great support of the land, and, possessing the intelligence to enact good laws, we lack the moral stamina to sternly and impartially enforce them. Law is the schoolmaster to train the people toward civilization. Had New York punished rigorously the little beginnings of fraud fifty years ago, it would have been a fiery ennoblement over the doorway to office, warning every man who would enter, that the way of the transgressor is hard.

Such men as Tweed, Hall, Duncan and Dorsey, and the host of wire-pullers, time-servers and political hucksters, who have their consciences for sale, know nothing of right as an abstract principle, as a law of duty whose throne is the bosom of Deity. The statute book is the only guide they recognize, and when it is inadequate or not likely to be enforced, then

the school master is asleep, the schoolhouse is closed, and lawlessness and crime have the State for a play-ground. Shakespeare says: "We must not make a scarecrow of the law, setting it up to fear the birds of prey, and letting it keep one shape, till custom makes it their perch and not their terror."

And what is our Penal Code, in many criminal courts, but a scarecrow that may frighten the poor and timid, but only excites the scorn and contempt of the bold and daring. The chances of escape for wealthy or influential criminals, through the delays of the law, defective pleadings, the conflict of authorities, tortuous construction, the technicalities of evidence, spiriting away or suborning of witnesses, and packing juries, have become so great that the punishment of Tweed stands out in forensic history as a solitary monument. And when such absconding defaulters as Gray are caught and convicted they are rarely ever punished in such a way as to make crime odious, and deter others from committing similar offenses.

On the Rhine.

Our engraving presents a scene on the river Rhine, famous in song and story, renowned in history and the pride of the later generations, the scene of ancient stirring deeds, and to-day the Mecca of the tourist who visits the continent of Europe. The Rhine has many moods to suit the conditions which are forced upon it.

A SCENE ON THE RIVER RHINE.

Along the frontier between Switzerland, Bavaria, and Baden its navigation is difficult, and in many places entirely interrupted by rapids and cataracts. There the Rhine is in his wildest mood. Again, on its lower levels from Cologne to the North Sea, the Rhine is a tame, sluggish water course, so lifeless as to almost sink from sight, losing its individuality in several uninteresting branches.

During its middle course the Rhine winds its way through a broad and fertile valley, which is called the garden of Germany. Again, after passing through a narrow gorge, it reaches a plateau, where the river becomes an important route of traffic and presents some of the finest and loveliest scenery in the world, flowing along between vine-clad hills, which now and then hem it in between steep towering rocks crowned with old castles, and again opens into long, beautiful cross valleys through which smaller streams come rushing.

Our engraving shows the Rhine in one of its quieter situations. There is an old dismantled castle, it is true, to remind one that the ground is historic, but otherwise the scene is one of quiet life, the barges upon the river suggesting productive farms and other industries near the river banks. The steam vessel below shows also that the traffic is not in small amount. The scene is a lovely one.

INTENSITY OF SOUND.—M. Allard finds intensity of sound decreases far more rapidly than the square of the distance law. One great cause of the enfeeblement is the non-homogeneous nature of the atmosphere.

If Prof. Kolbe is to be believed, an atmosphere of carbonic acid gas will preserve beef sound and in flavor for some weeks, but mutton treated in the same way turns offensive in the short space of eight days.

The Cattle Industry of the Plains.

It seems that shares in cattle growing companies are becoming the fashionable investments in New York as well as abroad. We recently gave some facts about the investment of British capital in building up live stock enterprises to Colorado, Wyoming and adjacent Territories, and how well the shareholders were pleased with their investments. In New York, on Monday evening, a group of New York cattle breeders had a banquet and a discussion afterward. James A. Burden presided, and introduced as first speaker Thomas Sturgis. To show the enormously rapid growth of the stock business in the West, he cited the Wyoming Stock-Growing Association, of which he was himself a member. Ten years ago it was organized with 10 members, representing 25,000 head of cattle worth \$500,000. Today it has a membership of 100, representing 1,000,000 head of cattle, and is worth \$30,000,000. Last year they sent to market 200,000 head of cattle, which netted to the owners about \$1,000,000. The four great difficulties they had to contend with were the Indians, the white outlaws and the thieves of the border, contagious diseases and the climate. The first three had been practically reduced to nothing by the association. They had their own police, watching every outlet by which cattle could be smuggled out of the country, and

The Mission of Labor.

Labor, like everything else, has an end in view. The first aim is to make a living. Man is a feeding animal, and that want is the spur that quickens his latent energies. Hunger drives the savage to hunting, fishing, grubbing for roots, or planting a patch of corn or potatoes. Unclement weather compels him to clean out a cave or hollow log, thatch a hut, and seek some rough material, a skin or blanket for clothing. Civilization began in want. It was born of a sensation, and received its first impulse from the thrill of a nerve. Carlyle poured his fiercest scorn on the philosophy of utility, which he called the "gospel of dirt," and the German philosophers satirized it as a "bread and butter science," all alike and forgetting or ignoring the fact, that their best thoughts have been transmitted in the mysterious alchemy of the brain from pork, beef, potatoes and bread.

But labor has a higher aim than merely to feed and clothe the body, and pick bed and board out of nature, and that is, to improve, idealize and perfect our work. With varied talents, and through diversified agencies, each one is called to work out his mission as a sculptor, architect, author, editor, singer, lawyer, doctor, preacher, farmer, or laborer at some trade or handicraft. But it is a duty that each one owes to himself and humanity, to do thoroughly whatever falls to his lot. It is a manly ambition to make the most of our calling, be it to shape wheel or horseshoe, drive a stage, sew a welt, or twist a whip cracker. Ambition to excel is the spring of all progress in the practical arts and inventions. It is the healthy spirit of emulation that gives us such wonderful improvements in machinery, model farming, fruit raising, live breeds of horses, cattle, sheep, hogs and poultry.

But there is a still higher aim in labor than merely to earn our daily bread, and excel in our special calling and wear the red and blue ribbon at our agricultural fairs. It should ennoble the worker, enrich his mind, sharpen his perceptions, store his memory, regale his imagination, elevate his aims, in short, make him a fuller, riper, better man. The world is a school. Every calling is to some extent a teacher in this school, and if the farmer, mechanic or tradesman does not make his special vocation contribute to his intellectual force and manhood, it is largely a failure. Every form of business has almost illimitable relations, runs into all sorts of complexities. Take farming, for instance; the farmer, in order to thoroughly master his vocation, should know something of chemistry, in its relation to the soil; the various breeds of horses, cattle, sheep and hogs; their diseases, and the best modes of prevention and cure, and a hundred other things in relation to the farm, garden, orchard or vineyard. Every corner grocery is an epitome of the world. The products of all the zones and climates may be found in the smallest establishment—sugar, coffee, tea, salt, fish, etc. Every article opens into an immense avenue of information to any one who would feel intelligently at home in his business. Any one can learn to raise wheat, barley, apples, strawberries, how to fit a boot, cut a coat, shape a hat, weigh drugs and groceries on scales, and pace through the drudgery and routine of each day's work, but only the man who is thoroughly master of his business in all details and relations will feel that sense of manliness and independence, that consciousness of knowledge and power that is always an un-failing source of pleasure and enjoyment.

RESULTS OF NEW INVENTIONS.—Mr. Edward Atkinson, illustrating the advantage of machinery, says it would require 16,000,000 persons, using the spinning-wheel and hand-loom of less than a century ago, to make the cotton cloth used by our people, which is now manufactured by 160,000.

STEEL AN ALLOY.—Prof. D. E. Hughes, F. R. S., recently read an important article on the molecular rigidity of tempered steel before the Institution of Mechanical Engineers. From the experiments he has made, he strongly favors the view that steel, when tempered, is an alloy containing fixed carbon in a far greater quantity than when soft.

BUTTE, with its Alice, Moulton, Lexington, and others, pours a steady stream of precious metals into the lap of the country, and will continue the same work, on a large scale.

they had organized a quarantine system which had effectually prevented the introduction of disease.

Mr. Dater said he believed the most profitable industry in the West would be the raising of horses and mules. Drayage horses and mules he claimed could be raised for not exceeding \$20 per head, and this would show even a greater profit than cattle raising.

General Grant gave some interesting reminiscences of the stock business in Texas, when, in 1845, he first visited that country, and still later, when he had gone through our cattle raising territories. He had believed that by this time that section of the country would be in the same state as the South American large ranch owners, raising cattle for the mere sake of getting the hides and tallow, but the wonderful development of our population and our prosperity had made this expectation fail of its fulfillment.

VEGETATION AT THE POLES.—The retreat of vegetation from the polar regions is attributed by M. M. Rey de Morando to the gradual decrease of the diameter of the sun. He thinks that the greater center of our system was once large enough to send its rays at the same time over both poles.

In a paper on the vertebrae of the Adirondack region, Dr. C. H. Merriam says that a panther, unless very young, or when pursued by dogs, never climbs a tree; but it has a power of bounding or leaping which is remarkable. It has been known to jump from 20 to 40 feet at a single spring.

SNAKE RIVER, Idaho, has commenced to rise, but it is thought there will be less water this season than usual, by reason of the slight snow fall during the winter.

Are Miners Human?

When we read such accounts as this given by Mr. Powderly who has visited the mines in Maryland and Pennsylvania, we are led to ask—"Does civilization demand that men, human beings, men who ought to be Christians—that men made in the likeness of God must be doomed to such slavishness, to such degradation, to such hopeless misery as this?"

"I was down in Maryland not long ago, and there I met a lot of miners who had been out on a strike. The company for whom they worked wanted to reduce their pay half a dollar a day, and clap on two hours of extra work upon them, on top of that. Naturally enough the men objected. If the men had been as well organized as they are elsewhere, the thing could have been regulated without a strike. They didn't think that there were miners working in another part of the country getting out the same coal and for the same market. The men struck, but the strike was a failure, as when the men came back they saw a new kind of labor introduced in the mine, a kind of labor against which they could not compete. Let me tell you about it. When I went to that mine in November last, I saw one of the new miners. He had on a blouse of jeans, reaching to the knee, and jean overalls. There were no socks on his feet, which made a strange noise when he walked. He was as black as his clothes, which were as black as the ten of spades, which is ten times blacker than the ace; and when he came from the hole in the ground where he worked, he went into a log shed, known as a boarding-house. It was 120 feet long, built of rough pine, and with a cooking apartment at the further end. There was room for 105 men in this place, which was the eating and sleeping-room. They slept in bunks about two feet wide, which were as black as the clothes of the miners, and the tables were of equal blackness. I saw that man go into that black den and eat a mess of meal and warm water, and then tumble into one of these black bunks to sleep. On Sundays as well as Saturdays these men tumble out of bed at daylight and go to work in that grim hole in the ground. What class of men are they, do you ask? They are imported Chinese coolies and Hungarians, held there in a species of slavery which is a crime in the face of our institutions and our laws. I was speaking of those shoes. Here is one of them (the speaker produced a hideous looking oaken shoe, weighing about five pounds, with iron-shod stilt under the heel and middle of the sole to keep the foot of the miner out of the water at the bottom of the mine.) And it is as hard as the heart of the men who force their help to wear them. These begrimed miners of whom I speak work for men who are rich and pious, who are pillars in churches, and strong as philanthropists. They pray every day, "Give us this day our daily bread," but there is no daily bread for the poor creatures who delve in the mines that they may have wealth. There is meal and water for them, blackened bunks and foul tables, and seven days work in the week. This is an existing fact, not in Siberia, but in the free America of to-day, and it is an insult to American manhood. It is slavery, worse slavery than that which the liberty loving North crushed out at a cost of half a million of precious lives, and billions of dollars of treasure."

Too Much Dreaming.

A New Yorker who spent several weeks in the Black Hills country last fall met with some rare chances as soon as he left Denver. The first took him aside and began:

"Say, stranger, are you after a mine?"

"Well, perhaps."

"Do you want the biggest spec. in the West?"

"I might take it."

"Then you lay low. A sick man over here has dreamed three times running of finding the richest silver mine in the world, and I'll get all the directions as to how to find it for \$500 cash down."

The offer was not accepted, and within a few hours a second party had a "find" on hand that his brother had dreamed out. The third man wanted to sell his father's dream for \$200, and the fourth had a dream of his own to sell cheap for spot cash. When the fifth one began negotiations the New Yorker cut him short with:

"Say, don't do it! you are the fifth man who has tried the dream business on me this week. Don't you do anything but dream out here?"

"Well, there's a good deal of dreaming around this locality," placidly answered the man—"in fact, too much of it. If some of the boys don't quit the business I reckon I'll have to go back to salting up mines and selling out to Chinamen."—*Wall Street News.*

AURORA BOREALIS (NORTHERN LIGHTS).—According to Nordenskjöld, the aurora borealis is a permanent natural phenomenon in the polar regions. It appears every night, and always in the same part of the sky. The center of the aurora is a little to the north of the magnetic pole, in a plane perpendicular to the polar axis. This would be something like one of Saturn's rings, but of a very different composition, and with frequent changes of brilliancy and form.

A new kind of alum, called double alum, has been introduced in the German trade. It is a transparent sulphate of alumina, but has a larger proportion of the latter than usual, and is free from iron and acids. For many industrial purposes, such as the preparation of paper, etc., it will, it is claimed, present some advantages.

USEFUL INFORMATION.

The Manufacture of Fireworks.

A visitor to one of those case making sheds, in which a good fire may be roaring in an open fireplace, will perhaps be rather startled to notice a number of barrels and jars. The receptacles represent the most modern development of the pyrotechnic art. Dip into this barrel and bring out a little of its contents on the point of a knife and hold it in the dark part of that gas flame. It is arsenite of copper and sal ammoniac, and instantly the light of noon-day is overpowered with blue glare. We make another dip and bring out a little chlorate of baryta, and a dazzling outburst of green is the result when placed in the flame. Here is a barrel of sal ammoniac which is combined with color giving substances to give depth and intensity. Another receptacle holds chlorate of potash, a source of oxygen gas, without a good supply of which fireworks can not be expected to be very bright. Some of the coloring substances are very perilous. If, for instance, a little of a compound of nitrate of strontia and sulphur and potash—the source of the most vivid red color known to chemists—should be left after a display, it is always either fired or buried. It is too dangerous to attempt to store. Fifty years ago colored fireworks were unknown, or nearly so.

The most delicate and interesting feature of modern firework making is the charging of Roman candles. The public like to see these balls thrown out with exactly an equal force so as to play within the same sphere. To secure this, very careful adjustment is necessary. The fiery balls of color are little lumps of composition filled into the case, and separated from each other by a layer of "dark fire," a little charge of gunpowder being just underneath. If all the charges were alike, every ball would be thrown out a little farther than its predecessor. To obviate this, the charge is increased as the tube is filled up. The workman, therefore, has before him a series of little scoops of different sizes for measuring the powder, the smallest being used for the first ball, and the largest one for the ball at the mouth of the tube.

Of all fireworks, the rocket is the most beautiful, and certainly is the most curious in structure. Some of them are said to rise to a height of more than a third of a mile, and this flight is secured by running in very tightly into the rocket case a composition which burns fiercely, and generates very rapidly when once lighted, but has only a very small vent for its fury at the lower end of the case. The gas instantly rushes out with such violence that the rocket is driven upwards by it, the tail consisting of the sparks of the fire burning within.—*American Inventor.*

TESTS OF DIFFERENT DISINFECTANTS.—A resume of the results arrived at by the St. Petersburg Academy of Science, in its investigations of the different antiseptic substances and disinfectants so called, appears to be somewhat at variance with opinions held elsewhere. According to the report given carbonic acid is most efficacious in preventing the formation of ammonia and the development of inferior organisms by the decomposition of organic matter, and it is, in consequence, the best antiseptic. Oil of vitriol, the salts of zinc and charcoal, are the most active for neutralizing the foul odors originating from putrid matter. Chloride of lime and permanganate of potassa act promptly in destroying the inferior organisms found in putrid liquids. Generally speaking, these disinfectants retard, in a measure, the development of putrefaction in organic matter, but their influence is only momentary; as regards the purification of apartments, their influence is but feeble, if not totally ineffectual, by reason of the small degree of concentration of their elements. For buildings not inhabited chlorine and nitrous acid are the best.

FLINT LOCK GUNS.—One of the most important of Birmingham industries is the gun trade. A very large number of shot guns go to America from here every year. Many fine fowling pieces are included, but still most of the guns are of a very cheap kind. A strange branch of the gun business here, says Consul King, is the manufacture of guns for the east and west coasts of Africa. These weapons are still made in great numbers, and usually have very long, bright barrels, and old-fashioned flint locks. It seems that the natives of the African coasts and interior prefer flint to percussion locks, because of the difficulty of procuring caps. The guns for this trade are very cheap, some selling as low as five or six shillings apiece at wholesale; but every barrel has to be tested at the Government proof house, the same as if intended for the finest of hammerless breech-loaders.

TO RENDER SILK LUSTROUS.—The following bath is recommended for rendering black dyed silk more lustrous and shining: Dissolve two pounds of soda crystals in ten gallons of water. To this bath olive oil is added in sufficient quantity, and until the oil begins to float on the bath. The addition of acids to this bath is not recommended, but if the silk has to be deprived of the whitish shine it acquires in the above bath, it can be washed in water in which citric, tartaric, or acetic acid has been dissolved.

NEW PRINCIPLE IN RICE MILLING. The *Sugar Bowl* call the attention of rice planters to an invention which introduces a new principle in substituting for the vertical movement in common use, whereby rice is decorticated by a species of pounding, a rotary motion wherewith the grains of rough rice are decorticated and polished through a simple friction with each other. The object sought is to avoid the breakage of grains and the pulverization of husks, which has cost so much time in winnowing and separation of the broken grains.

RUBBER LUBRICATOR FOR BELTS.—Five parts of India-rubber are cut fine and melted together with five parts of oil of turpentine in an iron well-covered vessel; then add four parts of resin, stir well, melt, and add four parts of yellow wax, stirring constantly while melting. This mixture while warm is added, with constant stirring, to a melted mixture of fifteen parts fish oil and five parts of tallow, and the whole is agitated until it has congealed. The mass is applied to old belts upon both sides in a warm place, and when the belts are in use, from time to time upon the inner side. By this treatment they become very durable.—*Chem. Centralblatt.*

ADULTERATION IN FLOUR.—The following mode of detecting adulteration of flour is furnished by a foreign correspondent: If flour is heated with 70% alcohol and 5% muriatic acid, the liquid remains uncolored if the wheat or rye flour is pure. It turns yellow if adulterated with barley or oatmeal, orange color with corn meal, and red with beans or cockle.

TO PREVENT THE HAIR FROM FALLING OUT, use a mixture composed of two ounces of spirits of ammonia, two ounces each of glycerine and rose water, one half ounce of cantharides and enough alcohol to clarify.

TO TAKE OIL SPOTS OUT OF MATTING, ETC., wet the spot with alcohol, rub it with hard soap, and then wash well with cold water.

GOOD HEALTH.

Should Men Cut their Hair?

A correspondent of the *Phrenological Journal* writes as follows:—Whether the hair should be cut I could never quite satisfy myself. As a phrenological practice, I seriously doubt the propriety. Every cutting is a wounding, and there is some sort of bleeding in consequence, and waste of vital force. I think it will be found that long lived persons most frequently wear their hair long. The enting of hair stimulates to a new growth, to supply the waste. Thus the energy required to maintain the vigor of the body is drawn off to make good the wanton destruction. It is said, I know, that after the hair has grown to a certain length it loses its vitality at the extremity and splits; whether this could be so if the hair should never be cut, I would like to know. When it is cut a fluid exudes, and forms a cicatrix at each wounded extremity, indicating that there has been injury.

I wish that science and civilization had better means for preserving the hair. Baldness is a deformity, and premature whiteness a defect. If the head was in health, and the body in proper vigor, I am confident this would not be. I am apprehensive that our dietetic habits occasion the bleaching of the hair. The stiff arsenic hat is responsible for much of the baldness. Our hats are unhealthy. I suppose there are other causes, however. Heredity has its influence. Certain diseases wither the hair at its roots; others lower the vitality of the skin, and so deplete the body. I acknowledge that the shingled head disgusts me. It cannot be wholesome. The most sensitive part of the head is at the back where the neck joins. That place exposed to unusual heat or cold is liable to receive an injury that will be permanent, if not fatal, in a short period. The whole head wants protection, and the hair affords this as no other protection can. Men have beards because they need them, and it is wicked to cut them off. No growth or part of the body is superfluous, and we ought, as candidates for health and long life, to preserve ourselves from violence or mutilation. Integrity is the true manly standard.

HEADACHE.—The *Boston Journal of Chemistry* thinks that the headaches that many thousands wake up with every morning are brought about by kerosene lamps "turned down low." A small flame in a lamp chimney does not cause enough draft to insure complete combustion, and slumberers breathe carbon and carbonic acid gas as literally as if they stood over the chimney of a petroleum refinery. A little light may be supplied in a bedchamber, if any is required, by a specially prepared taper, by a candle, or by a wick floated in animal or vegetable oil; but the turned down kerosene lamp can not be used except to one's discomfort. Dr. Haley says that as a rule a dull, heavy headache, situated over the brows and accompanied by languor, chilliness and a feeling of general discomfort, with a distaste for food, which sometimes approaches to nausea, can be completely removed in about ten minutes by a two-grain dose of iodide of potassium dissolved in half a wineglassful of water, this being sipped so that the whole quantity may be consumed in about ten minutes.

Growth of Hair and Nails After Death.

The following extract from the "Acts of Leipzig," may possibly be of interest: "In the year 1719 a woman was interred at Nuremberg in a wooden coffin. The earth wherein her body was deposited was dry and yellow. In 1761, the grave was dug up anew. To the surprise of the digger, he perceived a considerable quantity of hair that had made its way through the crevices of the coffin. The lid being removed, there appeared a perfect resemblance of a human figure, the eyes, nose, mouth, ears, and all other parts being very distinct, but from the crown of the head to the soles of the feet it was covered with very long, thick and frizzled hair.

The learned Honoratus Fabri (lib. 3, De Plantis), and several other authors, are of opinion that hair, wool, feathers, nails, horns, teeth, etc., are nothing but vegetables. If that be so we need not be surprised to find them growing on the bodies of animals after death, a circumstance that has occasionally been observed. Petrus Borellus pretends that these productions may be transplanted as vegetables and may grow in a different place from that where they first germinated. He cites in some observations on the subject, among other examples, that of a tooth drawn out and transplanted. [The transplanting of teeth has, of late years, become quite common.] In the "Philosophical Collections" of Mr. Hooke, it is stated that a man hanged at Tyburn for theft was found shortly after his removal from the gallows to be "covered over in a very extraordinary manner with hair."

In a letter addressed by Dr. Bartholin to Mons. Sachs, which is inserted in the "Acts of Copenhagen," occur the following words:

"I do not know whether you ever observed that the hair which in people when living was black or gray, often after their death, in digging up their graves or opening the vaults where they lie, is found changed into a fair or flaxen color, so that their relations can scarce know them again by such a mark. This change is produced, undoubtedly, by the hot and concentrated vapors which are exhaled from the dead bodies."

During the Crimean war an officer well known for his fine beard died, or was killed in action. He was buried, wrapped in his blanket. A little while afterwards his body was exhumed, for some reason, and it was said that his beard had grown through his blanket.

AN UNALTERABLE FACE.—There is said to be a man in Bellevue Hospital, New York, with a face that never alters its expression in the slightest degree. Something is the matter with the nerves and muscles so that they do not work at all. Not the faintest smile nor the suggestion of a frown ever varies the stolid monotony of his countenance. The features are regular and rather handsome, there being no distortion, or any outward evidence of the affection other than the strange immobility. His name is Henry Stube, but he is called "Masky," because his face is like a mask, behind which he laughs and weeps unseen. He has worn this mask of his for two years. He acquired it after a neuralgic cold. He is being treated with electricity chiefly, and the physicians think he will recover. In the meantime he parts his lips with his fingers for the introduction of food and water, and when he sleeps his eyelids are held shut by a slight bandage. His imperfect talking is done without moving his lips, and when he speaks or listens the impassiveness of his face looks singular, indeed. There is something uncanny about it, and, after the idea has once got into your mind, you can hardly regard this face as anything else than a mask.

A SINGULAR CASE.—Albert Duren, the great artist had to endure great grief on account of a singular manifestation of temper and conduct on the part of his wife. He finally sank under the affliction, when his wife becoming alarmed at his condition was able better to control her feelings and conduct, and did everything to aid and comfort him. During his sickness she, for the first time, told him the cause of her own trouble, which she had been unable to control. Her malady—for such it was—arose from a hurt in her head, which she received from a fall when quite a young girl. The injury, on examination, was perceptible to the eye in the form of a small depression. In certain conditions of the weather, particularly during the continuance of east winds, she suffered intensely in the head, which physicians attributed to chronic inflammation of the envelope of the brain, in the region injured. The diseased condition of her brain developed itself in the way and manner above described.

IMPORTANCE OF EXERCISE.—Dr. Cathcart, Lecturer on Anatomy in the Edinburgh School of Medicine, gives some striking facts as to the effect of systematic exercise in expanding the chest. At a school for boys where regular exercise was compulsory, new pupils, aged fourteen, were found to have an average chest measurement of 29.3; at fifteen they measured 30.16; at sixteen, 32; at seventeen, 32.6, and at eighteen, 32.5. Pupils who had been for some time in the school measured, at the same ages, 30.6, 32.1, 34.2, 35.8, and 36.8.

DEATH, in our view, takes place when the action of the heart ceases, but to the Chinese a person is alive until the body becomes cold. These two beliefs may cause estimates of the time of death of any individual to differ by several hours, which difference has given rise to some very unsatisfactory evidence at inquests in Hong Kong, the Chinese idea having been unknown to Europeans until very recently.

Saturday Morning, Mar. 31, 1883.

TABLE OF CONTENTS.

EDITORIALS.—The Southern Exposition; Smelting Copper Ores in Mexico, 217. A Great Legal Warfare, 218. Passing Events; Delinquent Mine Partners; The Solar Eclipse of May 6th; Mining Plants; Mine Timberlog, No. 6, 224. The Mining Bureau; Steel Wearing Surface for Ore Crushers, 225. Patents and Inventions; Notices of Recent Patents, 228.

ILLUSTRATIONS.—Mexican Copper Smelting Furnace; The Southern Exposition Building, 217. A Scene on the River Rhine, 222. Dodge's New Improved Rock Breaker for Mining and Engineering Use, 225.

CORRESPONDENCE.—Keep the Slickens in the Mountains, 218. Notes from Eureka, Nevada, 225.

MECHANICAL PROGRESS.—Resharpener Files; The Gas Engine; Steel Wire Pipes; The Corrosion of Iron and Steel; Monster Steam Whistles; A New Copper-Zinc Alloy; To Protect Iron and Steel from Rust, 219.

SCIENTIFIC PROGRESS.—The Movement of Water in Plants; Underground Temperature; The Red Spot on Jupiter; Use of the Microscope in Brewing; The Effects of Oil upon Waves; Water to be Carried as Gas, 219.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 220.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, New Mexico, Oregon and Utah, 220-21.

USEFUL INFORMATION.—The Manufacture of Fireworks; Tests of Different Disinfectants; Flint Lock Guns; To Render Silt Lustrous; New Principle in Rice Milling; Rubber Lubricator for Belts; Adulteration in Flour, 223.

GOOD HEALTH.—Should Men Cut their Hair; Headache; Growth of Hair and Nails after Death; An Unalterable Face; A Singular Case; Importance of Exercise, 223.

MISCELLANEOUS.—Official Villains on the Rhine; The Cattle Industry of the Plains; The Mission of Labor, 222. Are Miners Human?; Too Much Dreaming, 223.

NEWS IN BRIEF.—On page 228 and other pages.

Passing Events.

For California, we have had a great event, and one long looked for, but nearly given up—that is, a rain storm. The long continued dry weather has been bad for miner, farmer, and the whole community. Many persons had fears of a very bad year to come, but the long expected rain has banished all fears, and given rise to great rejoicing on all hands. The downpour has been general, and has not been niggardly. An abundance of water has fallen. The mining and agricultural communities both are benefited, and the whole State is a gainer by millions of dollars.

From the mining regions there is little news of moment. The storm will set back prospecting a little in some regions, but in others it will forward it. The ditches will now be running full, and a good season may be expected.

For the third or fourth time in the history of the Comstock, buildings are being removed and hauled to and set up in new camps. In 1863 a number of buildings were torn down and taken to Reese River, Austin. In 1865 Meadow Lake came in for a share of the Comstock houses. In 1869 houses were torn down and hauled from Virginia to White Pine. This time houses that are useless on the Comstock are being hauled to Hawthorne, the coming metropolis on the line of the Carson and Colorado railroad.

A NUMBER of Comstock prospectors are preparing to go out into the new country at and about the present terminus of the Carson and Colorado Railroad.

Delinquent Mine Partners.

There is no greater nuisance than for a miner to get a partner in a claim with him who will not do his share. Under the old laws it was quite difficult to get rid of him, and even under the provisions of the existing laws there are certain forms which must be gone through, which take time and are of more or less trouble. Still there are means of ridding one of a non-paying partner. These means we detailed at some length a few weeks since. It must be remembered, however, that the U. S. mining laws provide only for removing a partner who fails in paying the required expenditures—that is, what the U. S. laws require—and as far as not paying the actual expenditures recourse must be had to the courts.

There are some other details which mine owners afflicted with delinquent co-owners should remember, and more especially when they are going to patent their claims. Where a party proceeds against one or more of his co-owners, under the U. S. mining laws, he should file with his application for patent a copy of the original notice of location; an abstract of all conveyances made of the claim; a copy of the notices published to delinquent co-owners—which notice should embrace the names of all delinquents—to which must be attached the affidavit of the publishers of the paper in which the notice was inserted, that the attached notice was published for the period of ninety consecutive days, giving dates; the affidavit of the claimant or claimants who have made the required expenditures, corroborated by the sworn statements of two or more disinterested witnesses, showing the character and extent of the improvements made upon the claim, and the time when the improvements were made. There must, also, by the rules of the Land Office, be filed, the sworn statement of the claimant or claimants who had made the required expenditures, as to whether or not either of the parties whose names appear in such published notice, contributed his proportion of the required expenditure, either during the ninety days' notice by publication, or the succeeding ninety days. The evidence must be full, positive and explicit on all these points. Miners applying for patents should call the attention of their attorneys to any delinquency of partners at any time previous, in order that all these precautions may be taken, and the time, expense, and annoyance of a rejection may be prevented.

Mining Plants.

Perhaps as much harm has been done to the mining industry in the matter of making mistakes about new plants of machinery for mines as in any other way. The advisability of placing a limit on the otherwise costly business of putting down new plants is a subject seldom properly discussed by large companies. It is not always a recognized necessity to have accurate calculations made beforehand as to the proper size, strength and description of machinery, etc. Of course, the foundrymen know how to make the machinery so that all that part will be all right, but they build to order, and it often happens that very big machinery is made for very small mines. The advice of competent and experienced men should always be taken, and the whole subject be very thoroughly canvassed before active steps are taken. The makers of machinery in this country are skilled in their work, and with their varied experience are familiar with the best forms of mechanism which have proved successful.

At a recent meeting of the "North Staffordshire Institute of Mining and Mechanical Engineers," Mr. James Lucas, the newly elected President of the Institute, gave some views on this subject, more particularly with reference to the forms of machinery, appliances, etc., in use in collieries there.

Regarding winding engines he considered that vertical were far preferable to horizontal, although the first cost was considerably more, as there was not nearly so much wear and tear—for instance, they avoided any piston drag. There was an idea now afloat, that in the case of a horizontal engine, the piston swam in the steam in the cylinder. This might be perfectly true in theory, but from practical experience there was no doubt that such was not the case; he also found from experience that the more they could simplify the machinery the better it acted. As to ropes, it was first of all necessary to determine the proper strength of rope required to do a certain amount of work, and also if iron or steel would be best under the peculiar circumstances. Drums were

as important a part of the winding machinery as anything else connected therewith. For his own part he considered (if round ropes were used) that a drum of a slightly conical shape—say one in four—was best; and in all cases it was very necessary for the rope to coil on timber. If they had water to deal with in any quantity, it was most important that the utmost care should be taken to determine the best winding or pumping appliances which would be suitable to the task. If it was decided to pump the water, in his opinion a direct-acting engine was the most economical and efficient in its action.

As to the pumps, it then remained to be decided whether it was advisable to use rams or lifting buckets, or both; the description and strength of trees; the class of joint best suited to resist the pressure; the sort, size, and position of clacks, so as to be easy of access in case of any repairs being needed; and lastly, but not least, it was indispensable that all the trees and fittings should be tested before being put in, but not up to such a pressure as to strain them, as over testing was liable to produce permanent defects. It was very necessary for the safe and successful management of a mine that it should be laid out and ventilated in a thorough, workmanlike manner, for the safety of the men should always be the manager's first care. The speaker remarked upon the need for continual vigilance on the part of the mine management, to avoid waste in getting, and in the use of, stores of various kinds.

Mine Timberlog—No. 6.

Economizing Timber in Mines.

One of the great items of cost in mining operations is the timber. This, of course, depends greatly on location of the mine with relation to railroads or timber supply. But in any case in the employment of so costly a material as timber it is important that every means should be adopted for reducing the quantity required. It is, of course, impossible to proportion the dimensions of the timber to the strains to which it will be subjected, for the reason that these strains are wholly unknown. The pressure which a descending mass of rock will exert cannot be estimated; all that is known about it is that it may be very great, and hence an excess of material is placed to resist it. But though we are unable to economize timber in these directions, some reduction of the quantity may be obtained by a little attention to the rudiments of the resistance of materials. An observance of fundamental principles will here enable us at least to get from the timber employed the greatest resistance of which it is capable.

The materials of which the supports in a mine are composed may be subjected to a crushing strain in the direction of their fibers, or to a transverse breaking strain, and it becomes important so to place the pieces relatively to the strains to be thrown upon them, that they may be capable of offering the maximum resistance. If the strain is one of compression, it will be best resisted when it acts in a direction parallel to the fibers of the wood, and to secure this condition the support should be placed so that its length may be exactly in the direction of the pressure. Thus, in inclined seams, it is desirable to place the props at right angles to the floor, that is perpendicularly to the planes of stratification. As, however, the roof will sink slightly in spite of the prop, the latter may be made to deviate very little from the perpendicular in the direction of the vertical. If the pieces are long it may be necessary to stay them in the middle to prevent yielding by flexure. When the strain is transverse, the length of the piece should be reduced as much as possible by supporting it at frequent intervals, and care should be taken that it rests evenly on the supports. Provision should be made for distributing the pressure equally throughout the length of the piece by inserting wedges where the rock does not bear. These are principles which any intelligent and experienced miner may understand and apply. Such a man will see at a glance where the pressure comes from, and determine in a moment the direction in which the axes of his timber should be placed so as to resist it most effectually.

As mining timber is generally purchased in considerable quantities, it is important to its preservation that it be perfectly stored or sheltered from the weather. Where possible, a covered building should be chosen, and means of ventilation provided. Large pieces may be stacked horizontally and crosswise, but smaller ones are better placed on end. It is needless to remark, that in using from such a store the oldest pieces should be chosen first. Young trees are to be preferred to the tops of old trees, which are spongy in texture, and less resisting and durable than the lower portions.

The Solar Eclipse of May 6th.

EDITORS PRESS:—In my recent letter, I believe I was under the impression that the largest of the Tonga Islands, Tongataboo, and Eoa ten miles southeast of it, were included in the belt of totality of the solar eclipse of May 6th. Upon laying down a small sketch, which I enclose, and some larger maps they best explain that Flint, Caroline and Masse or Hiavo, the latter on the north of the Marquesas group, can be alone included. Hiavo is, I believe, about 140° 30' west longitude from Greenwich, and 7° 50' south latitude; Caroline island about 150° 30' west longitude and 3° 50' south latitude, and Flint island about 152° west longitude and 11° 20' south latitude. There must be some discrepancy in Lippincott's longitude of Hiavo, as it differs essentially from the position given by Capt. Wilkes in his chart of the United States Exploring Expedition, as well as Colton's Atlas enlarged group of the Marquesas. I have, therefore, preferred to adopt the position given by Wilkes and Colton.

The route from the east via San Francisco seems preferable to Panama for Hiavo, being only about 2,800 miles from San Francisco; a first-class steamship if chartered for the purpose need not take more than nine or ten days, which, with seven days from New York by railroad, makes seventeen days, while the New York papers reported that Prof. Halden and party left New York March 24, and expected to reach Callao by the 22d, and then it would take twenty-five more days by ship, a Government vessel, to Caroline island, making forty-five days compared with seventeen via San Francisco. Caroline island is also 600 miles further than Hiavo or Masse.

Sacramento, March 27th.

An Important Mining Case.

The case of the Boston and Arizona smelting and reduction Company against the owners of the Merry Christmas mining claim, just tried and decided in the district court here, is, perhaps, the most interesting case that has been tried in this county, by reason of the questions of law involved in it. It has attracted great attention, particularly from mining men.

The plaintiff owns the Knoxville mine, and brought suit against the Merry Christmas to try title to a portion of the Knoxville ground, covered by the Merry Christmas. The Knoxville was located May 6, 1868, and the Merry Christmas December 25th of the same year. The plaintiff urged that the Knoxville was a valid location, and that the ground in dispute was attempted to be located by the Merry Christmas while the Knoxville was a lawful and valid location, and that, by reason of this fact, the Merry Christmas location was invalid at the time it was made, and being invalid at that time, could never become a valid claim under the original location, even if the Knoxville claim should afterwards lapse, by reason of any subsequent failure to comply with the requirements of the law.

The Merry Christmas, on the other hand, urged that the Knoxville was not a good location under the law, by reason of the fact that the claim was not completely monumented when located, and that even if it had been, the plaintiff could not recover because defendant had been in adverse possession of the disputed ground for more than two years.

The court charged: That if the initial and end monuments of the claim were put up at any time before the Merry Christmas was located, the location of the Knoxville was good against the Merry Christmas, and if it was good, the location of the Merry Christmas was illegal and void, and never could become valid under that act of location, and consequently, the statute could not run in favor of the Merry Christmas as against the Knoxville. Verdict for the plaintiff. —*Tombstone Republican.*

The Supreme Court of the United States has dismissed, with costs, on motion of counsel for the applicants, the following well-known California cases, viz.: J. C. Flood et al., appellants, vs. John H. Burke; J. W. Mackay and J. G. Fair, appellants, vs. John H. Burke; J. C. Flood et al., appellants, vs. John H. Burke; and J. W. Mackay and J. G. Fair, appellants, vs. John H. Burke.

THE southeast drift on the 2500 level of the Con. Virginia is very hot. Not much work has been done in the face during the week. A cooling-house has been constructed out near the front and a second air pipe carried in. As it was the men had so far to travel back through the drift after cooling off that they were about as badly off when they got back to the face of the drift as they were when they left it.

A GOOD FIND.—The Sierra county Tribune says: Three yeast powder cans, filled with gold, were found yesterday among the ruins of the Hald Mountain Co.'s office at Forest City. It is not known how the gold came there, and the members of the company are completely mystified. They believe that it was placed under the building previous to the fire, as it could not have been secreted in the office.

THE flow of water from the Sutro tunnel is over 1,000,000 gallons, in twenty-four hours, more than it was a week ago.

The Mining Bureau.

We have several times referred to the fact that the State Mining Bureau was short of funds, and that the Legislature was to be asked to appropriate an additional amount to that yielded by the tax on the transfer of mining stocks. The Legislature appropriated \$10,000 for two years. The lowest income yet experienced from the tax on mining stocks is some \$400 per month, so the legislative appropriation makes the total income something over \$800 per month. The State Mineralogist states, however, that this is not sufficient, and makes an appeal to enable him to keep the museum open. In answer to circulars sent out to mining men the following gentlemen were present at the meeting of the Bureau on Monday: Melville Attwood, W. M. Bunker, J. H. Carmany, William T. Coleman, J. L. Davis, W. B. Ewer, S. Heydenfeldt, Jr., J. M. Keeler, J. M. McDonald, George T. Marye, A. B. Paul and Charles M. Tyler. Mr. Coleman was called to the chair, and Mr. Heydenfeldt acted as Secretary.

Mr. Hanks, the State Mineralogist, read an address detailing the work done by the Bureau, and describing the rigid economy which had been practiced to keep the institution running. He states that it is the experience of the management that the original Mining Bureau fund

for study and reference. This has already been done largely, and can be increased to an almost unlimited extent if the necessary funds can be made available. In consideration of the facts herein stated, I feel it to be my duty to appeal to the citizens of San Francisco and the State before taking the responsibility of closing the Museum.

After discussion of the affairs of the Bureau, a committee of five was appointed, consisting of Messrs. Paul, Heydenfeldt, McDonald, Bunker, and Tyler, as a committee of ways and means, to devise some plan of appealing to the citizens of the State to come forward and assist in maintaining the Mining Bureau until the next session of the Legislature.

Notes From Eureka, Nevada.

[From Our Regular Correspondent.]

EDITOR'S PRESS: Nothing unusual has happened during the past week in our quiet camp. All our matters are in the same state as they were a week ago, but it is thought that a settlement may be made in a few days. The new machinery at the Eureka Con. mine, I am informed, has also been paid for. The assessment was levied for prudential reasons, the company believing it better to have reserve funds in their treasury than to be in debt. Considerable interest has been shown during the past few days

limestone. Open seams occur in this, and the ore is found close to them. A short distance below the Dug-Out dump is a tunnel entering the hill, and running 150 feet N. 70 E., which has passed through a wide fissure filled with wash and cement. This measures seven feet between the walls, and, it is thought, will prove the main fissure upon which the ore will make great depth. Lower down on the hill is another tunnel, now in about forty feet. Near the entrance is a well defined quartz vein, showing a large proportion of antimony, which strikes N. 15 W., and dips northeasterly into the hill. No assays have yet been had from this, but, judging from appearances, it is also a valuable discovery.

In order to explore the mine at as great a depth as possible without the aid of machinery, as well as to make access to it easier than at present, a tunnel has been driven into the hill near the base, commencing on a location known as the "Trail," and running N. 10 E. 180 feet. At the face the rock, unlike the cap, is soft and broken. In it are small veins and seams of ore, that are evidently thrown out as feeders from a main channel further in toward the center of the hill. A lateral drift has been commenced from this tunnel and is now in 100 feet. It is intended to intersect both the quartz vein above mentioned, and the main ore fissure. It will probably tap the latter at a depth of 300 feet from the surface. As the section of

and Pacific Tunnel Co. adjoin the Excelsior, and likewise contain large bodies of ore. Both are mainly low grade, dry ores (i. e., not containing any lead.) It is probable that a process will be found by which they may be worked to advantage in the future, and it is my intention to make proper inquiries in relation thereto.

At the Herculean mine, on Adam's Hill, a great improvement has taken place lately in the quality of the ore, and judging from the immense deposits it will develop into a very valuable property. The Oriental and Belmont mine, also on Adam's Hill, has been bonded for sale to San Francisco people. This is a valuable property; the title is good, and it has produced quantities of ore from time to time, aggregating not less than \$200,000. Yet at no one point has a depth below sixty feet been attained.

The Rocky Point mine, on Hoosac Mountain, has been leased to a party of practical miners for six months, with the privilege of one year. Some very high grade ore has been taken from this property, and the formation is favorable for a good deal more.

At the Geddes and Bertrand mine in Secret canyon, Burleigh drills are to be introduced for the purpose of driving the tunnel from the mill to connect with the 150-foot level of the mine. The length of the tunnel will be 900 feet. The Bertrand Co. shipped last week, thirteen bars of refined silver bullion containing 10,653

DODGE'S NEW IMPROVED ROCK BREAKER FOR MINING AND ENGINEERING USE.

can not be depended on, and should not be taken into future calculations.

He says: "The appropriation by the last Legislature will suffice for the rent of a suitable office, for traveling purposes, the making of creditable reports on the mineral resources of the State, a continuance of the correspondence, and the care of the collections, but it will not support the present museum. The transfer tax will pay all the expenses of the contraction and leave the appropriation intact, unless it should diminish more rapidly than is now anticipated.

"It has long been evident that the State Museum was becoming too extensive and valuable to be managed by a single individual. The experience of the last three years has shown that there is a great future for the institution, if properly managed, and it is well worthy of the fostering care of the State. But it has already become so extended in its scope that any person familiar with the facts would be eminently conceited who would undertake to manage it without the advice and assistance of others. Under this conviction I asked, in my report to the Governor, 'that a Board of Trustees be appointed to share the responsibility and management of the State property, leaving the State Mineralogist free to travel, to investigate and report upon new discoveries, and to conduct the scientific departments with his assistants.' This was recommended by the Governor in his message, and, although no action was taken, I am still as strongly impressed with its importance as before, and for this reason I have asked you to consult with me, and to advise me what to do under the present circumstances.

"It is the province of the State Mining Bureau to seek locations of new minerals having an economic value, to learn their quality and extent, and to place specimens in the Museum

in some small specimens of wire silver that were brought in from

The Dug-Out Mine.

I visited the property to-day. It is situated on the southern portion of Prospect mountain, at a point where the latter joins the Spring Valley range. It was located in August, 1879, and since then considerable development work has been done. It was discovered by tracing rich float-rock, and the Dug-Out mine was duly located. The vein, at the point of discovery, was eighteen inches in thickness. Assays of the top rock ran from \$50 up to \$1,159 per ton. The first shipment that was sent to the furnace worked at the rate of \$241 per ton, and sufficient of this was taken from the surface to realize for the owner \$3,000 net before a hole even three feet deep was sunk upon it. A fine pocket of ore was found directly beneath this, which realized \$10,000 net.

Another pocket or chamber has also been opened from the surface. The latter is about forty feet long, twenty feet high, and vein about six feet in thickness; the pulp assays from the ore sent to the furnaces went from \$34 up to \$258 per ton. Still another chamber beneath the latter was emptied of its treasure, and it has since been filled up with waste rock. How many more pockets are yet to be discovered in this mine remains to be seen; no one can see in a mine beyond a pick's point. Fully 100 tons of ore, chiefly high grade, has been taken out, and now awaits shipment to the smelters. At points close to the surface there is still ore remaining in place, and from one of these I secured some very nice specimens, having an appearance similar to very small tufts of grass sprouting from the rock, but differs, inasmuch they are of pure white wire silver. The country rock near to the surface is very hard, white

country in which the Dug-Out mine is located is comparatively a

New One to Prospectors.

It is probable that it will soon become a point of great interest to mining men in this locality. At the Great Republic mine on the west side of Prospect mountain 150 tons of ore awaits shipment, and at the Banner are 160 sacks of good ore which will be sent to the furnaces in a few days.

At the Dug-Out mine, adjoining the Banner, a new strike has been made on the main tunnel level of from three to four feet in thickness, of rich, bright, carbonate ore. On a level sixty-five feet below the tunnel is what appears to me to be the most promising part of the mine. The formation is large, and shows evidence of more extensive ore chambers than any that have been discovered above it, iron and low grade ore showing in beautiful proportions. At the Industry mine, a fine vein of quartz ore has been discovered from the surface. This is a valuable property, and one that has seldom been out of ore since the day it was located, which was early in the year 1869.

The new engine at the Eureka tunnel is being set in place. There is no change apparent in this mine. Ore shipments are being made regularly, as usual. At the Vanderburgh mine, a new location, there is a good prospect in a drift west from the shaft, now down sixty-five feet from the surface. The drift is in ledge matter fully twelve feet in thickness, and valuable developments are anticipated. Tributaries are at work in the Excelsior mine, following veins of ore that work from \$100 to \$130 per ton. There are large bodies of ore in this mine that have been developed from the surface to a depth of nearly 800 feet, but which do not pay to work at present. The mines of the Atlantic

ounces. Twenty-eight thousand seven hundred and eighty-one pounds of ore shipped last week from the Silver Nugget mine on Silverado mountain, Pinto district, to the Richmond furnaces yielded from \$55.73 to \$281.08 in silver, per ton, and forty per cent. of lead.

In my next I shall endeavor to give you a particular account of the Ruby Hill mines.

M. H. JOSEPH.

Eureka, Nev., March 26, 1883.

Steel Wearing Surface for Ore Crushers.

Miles B. Dodge, of this city, obtained last week, through the MINING AND SCIENTIFIC PRESS Patent Agency, two patents for improvements on his rock breaker, which has been so many years in use. Both patents covered means for increasing the durability of the faces of the jaws. The engraving presented herewith shows the preferred form which Mr. Dodge some little time since adopted.

It will be seen that the wearing plates are studded with hardened steel pins, put in thickly in a plate of wrought iron. The plate wearing away from the steel pins leaves them projecting as high points thus splitting the rock in pieces with very little power. The plates last very much longer and more effective service is obtained from them. This cut represents the No. 2 rock breaker, but with the other three sizes two fly-wheels are used. The No. 3 is 6x7 for the assaying and sampling. The size shown is for ordinary mills. The No. 1 is 12x9 for heavyest mills; and the No. 0 is a big one, 24x20, for macadamizing, coal breaking, etc. With the steel-studded wearing plates, these machines are extremely durable.

Metallurgy and Ores.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. SLAG POTS AND CARS, IMPROVED FORMS. BULLION AND COPPER MOUNDS AND LADLES, LITHARGE CARS AND POTS, CUPEL FURNACES AND CARS.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Olan and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x30. BOILERS of every form, made of Pine Iron Works O. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs., heaviest pieces, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

SAW MILL CARRIAGE.—Caspar Schoch, Truckee, Placer Co. No. 274,227. Dated March 20, 1883. This invention relates to new and useful improvements in traveling carriages, and automatic block-sets for saw mills. The improvements consist generally in a novel means for reciprocating the carriage and regulating at pleasure the length of its travel, and in a novel means for setting over after each cut the block or timber for a new cut. More especially the invention consists in a double rack upon the carriage, an adjustable spur gear adapted alternately to enlarge either directly or indirectly with each of said racks to advance or return them, a trip lever to which said spur gear is attached, and suitable catches engaging therewith, and stops to trip the catches, whereby, at the end of each stroke, the trip lever is vibrated to throw its spur gear in and out of engagement with the racks; further, in a pawl and ratchet mechanism operated by a swinging arm engaged indirectly by a weighted lever, and moved by its fall when released at the end of the return stroke of the carriage, whereby the block or timber holder is set over for a new cut; further, in the adjustability of certain of the catches and stops, whereby the stroke of the carriage may be lengthened or shortened. The object in this invention is to provide a ready and effective means for automatically reciprocating the carriage and setting over the block, and to dispense with the weight which is ordinarily used to return the carriage.

TWO-WHEELED VEHICLES.—Geo. W. Dalton, Tomales, Marin Co., Cal., assignor of two thirds to L. Guldayer and M. L. Murphy, of the same place. No. 274,183. Dated March 20, 1883. This invention is intended to overcome or prevent the unpleasant motion which is usually transmitted to the seat of two-wheeled vehicles by the joggling motion of the horse. There are certain details of construction to provide a vehicle which will be easy on both horse and driver. The axle and shafts are connected together by coiled springs, coiled in opposite direction. The body is made to hang down as low below the pivoted line as possible, giving it stability by force of gravity. This is done by clipping the side spring below the axle, by regulating the length of the iron shafts on which the body is hung to the ends of the spring bars, and by making a recess in the bottom of the body. The body has such stability in this position by force of gravity that the side springs, the front and rear springs, the shackles and the double coil springs, connecting each shaft with the axle, yield sufficiently to save the body, and prevent it from receiving any of the unpleasant motion it is desired to avoid. The shafts when connected with the axle by the coil springs, do not by their up and down motion cause the axle to rock as they would if they were immovably fastened to the axle; and the body is so connected with the axle by intermediate devices that by reason of the character of such devices, by reason of the position of the body, and by reason of the coil springs connecting shafts to axle, the up and down motion of the shafts is not communicated to the body.

STOP VALVE.—Thomas Hennessey, Oakland. No. 273,839. Dated March 13, 1883. This invention relates to certain improvements in valves for water-closets, basins, etc., and is more especially applicable to a device previously patented by the same inventor. It consists in certain details of construction, embracing an adjustment of the spindle to regulate the opening of the valve, a removable valve seat, and a valve seat chamber made independent of the

upper part of the cork, a spring to hold the valve to its seat, and a transparent chamber through which to inspect the interior.

TWO-WHEELED VEHICLE.—Henry D. Page and Wm. E. Raynor, San Bernardino, Cal. No. 274,217. Dated March 20, 1883. The essential feature of this invention is that the shafts or thills, instead of being one single, rigid piece throughout their length, are severed at a point forward of the wheels, and near, or even beyond, where the front part or edge of the foot rest should naturally come. The severed ends of the shaft overlap some little distance, and are connected by a hinge or knuckle joint formed in any suitable manner. The effect of this divided and hinged shaft is said to prevent the action of the forward part from being transmitted to the after part and thence through the axle to the body.

STEAM COOKER.—Anna Sherman, Alameda. No. 273,901. Dated March 13, 1883. This vessel for cooking purposes is especially adapted to be used in connection with a tea-kettle for producing the necessary heat. It consists of one or more containing vessels, fitted vertically, and having a central tube projecting from the bottom, and also extending up into the vessel, so as to form an annular chamber around the tube within the vessel. Around the lower part of the tube is a flange, which supports the device, and forms a cover for the kettle below. Perforated gratings are fitted to the annular space, and bridges across the top of the tube serve to support other vessels within the outer one.

RAILROAD SWITCH.—Wm. McCall, S. F. No. 273,865. Dated March 13, 1883. This invention relates to certain improvements on the construction and operation of street railroad switches. It consists in the formation of the switch rail, of an attachment to it, by which the passage of the car is made to change the position of the rail, so that a car will be directed upon either branch of the track. There is a double inclined, arrow-headed plate secured to the bottom of the rail at the point and running in a recess or channel, so that its inclined sides may be acted upon by an arrow from the passing car to force it to either side, and thus direct the car to the desired line of rails.

GAS MACHINE.—Garritt P. Judd, assignor to Henry Phillips, S. F. No. 273,852. Dated March 13, 1883. This invention relates to certain improvements in that class of apparatus in which gas is produced from naphtha, gasoline, and similar substances for heating or lighting. It consists in certain novel combinations of parts. The object is to thoroughly saturate the air in passing through the machine, with the vapor of the naphtha or gasoline, and then to remove the surplus liquid, so the resultant gas will burn readily. Foraminous chambers are placed in a receiver, and the air passes through them to the discharge pipe.

TWO-WHEELED VEHICLES.—John A. Bilz, Pleasanton, Alameda Co., Cal. No. 273,804. Dated March 13, 1883. The principal features covered by this patent are details of construction in the vehicle previously patented by the same inventor. In this the body is given great independence of the shafts. Not only are the springs and axle hinged to the shafts, but the body is hinged to the springs, thus giving to it a freedom which prevents it from having to follow the shafts in their up-and-down movement, thus making it an easy-riding vehicle.

THE *Silver State* says that J. H. MacMillan has received a dispatch from the Secretary of the Auburn M. and M. Co., at Chicago, requesting him to have the company's horses fed for work, as McAllester and Rogers leave Chicago Monday to start up the mill and mine.

THE only iron preparation that does not color the teeth, and will not cause headache or constipation, as other iron preparations will, is Brown's Iron Bitters.

Our Agents

OUR READERS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.
 G. W. McGREW—Santa Clara county.
 M. P. OWEN—Santa Cruz county.
 J. W. A. WRIGHT—Merced, Tulare and Kern counties.
 JAMES C. HOAG—California.
 B. W. CROWELL—Arizona Territory.
 N. H. HAROOD—Plumas county.
 M. H. JOSEPH—Yureka, Nev.
 GEORGE McDOWELL—Sonoma county.
 F. W. STRATTON—Calaveras and El Dorado counties.
 I. M. LEHLY—Los Angeles and San Bernardino Counties.
 J. M. LEHR—San Diego county.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year.

N. B.—Personal attention will be called to this (as well as other notices, at times) by turning down a leaf.

Gold Mines of San Luis Obispo.

On Monday last we were shown by Mr. Cerf, of Blochman & Co., a fine lot of several hundred dollars worth of gold dust from the mines of La Panza, in this county. In the receipts of bullion at San Francisco, as reported annually by various statisticians, the name of San Luis Obispo never appears, and thus in the report sent abroad one—as many others are—of our important interests, is neglected. Our people have been content in having our great butter and cheese interests reported, and our beans and corn and wheat and wool, and that this shall be classed simply as a good "cow county," but we will now protest against the farther ignoring of so important an interest as our gold mining is and may become. Throughout the San Jose mountains, between the Salinas and the San Juan rivers, gold is found, and where water is obtainable can be mined with profit. On La Panza, Navajo, Montezuma and other streams of that region, mining has been carried on quite extensively, and during the gold excitement of 1878-79 several hundred were engaged in washing for the precious metal. Numerous quartz veins have been found showing gold, but no machinery has been erected for crushing the ore. The gold is altogether obtained from the placers by cradle and sluice washing. The want of water is the chief obstacle to successful mining. The annual product, unless the drought prevents work, is about \$10,000. During the excitement above referred to the product reached \$50,000 to \$60,000 per annum. With such a bullion product we claim the attention of the San Francisco statisticians for a place in their reports. Put the county down as producing \$10,000 of gold dust annually; also some \$60,000 worth of chrome iron ore, and possessing immense deposits of quicksilver, copper, ore, gypsum, onyx, alabaster and asphaltum. If San Luis Obispo is a first-class "cow county," so is it able to take high rank in mining, as the mineral resources are of a wonderful rich and varied character.—*Tribune*.

News in Brief.

TWENTY-TWO ostriches, for the ostrich farm near Contra Costa station, Los Angeles county, have arrived safely at their destination.

At Winnemucca, Nevada, a woman serving a sentence in jail for whipping her husband, secured a divorce on the ground of extreme cruelty on his part.

SEVERAL localities at the foot of Mount Ararat have been destroyed by snow avalanches. It is stated that 150 persons have been killed and 100 injured.

THE *Shasta Courier*, a very good exchange and the first number of which was published on March 12th, 1882, has begun a new volume.

TWO THOUSAND infantry have been ordered to protect public buildings in London. The Coldstream Guards have been posted in the Parliament buildings and Buckingham Palace.

A SHOSHONE INDIAN stoned his young step-daughter to death near Belmont, Nev., last week. It is stated that the girl is the sixth victim of the murderous savage during the past five years.

THE answer of Prussia to the note of the Papal Secretary of State refuses to concede the demand relative to the education and appointment of priests. The negotiations thus far have been a failure.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

STRONG FACTS!

A great many people are asking what particular troubles BROWN'S IRON BITTERS is good for.

It will cure Heart Disease, Paralysis, Dropsy, Kidney Disease, Consumption, Dyspepsia, Rheumatism, Neuralgia, and all similar diseases.

Its wonderful curative power is simply because it purifies and enriches the blood, thus beginning at the foundation, and by building up the system, drives out all disease.

A Lady Cured of Rheumatism.

Baltimore, Md., May 7, 1880.
 My health was much shattered by Rheumatism when I commenced taking Brown's Iron Bitters, and I scarcely had strength enough to attend to my daily household duties. I am now using the third bottle and I am regaining strength daily, and I cheerfully recommend it to all.
 I cannot say too much in praise of it. Mrs. MARY E. BRASHEAR, 173 Prestman St.

Kidney Disease Cured.

Christiansburg, Va., 1881.
 Suffering from kidney disease, from which I could get no relief, I tried Brown's Iron Bitters, which cured me completely. A child of mine, recovering from scarlet fever, had no appetite and did not seem to be able to eat at all. I gave him Iron Bitters with the happiest results.
 J. KYLE MONTAGUE.

Heart Disease.

Vine St., Harrisburg, Pa. Dec. 2, 1881.
 After trying different physicians and many remedies for palpitation of the heart without receiving any benefit, I was advised to try Brown's Iron Bitters. I have used two bottles and never found anything that gave me so much relief.
 Mrs. JENNIE HESS.

For the peculiar troubles to which ladies are subject, BROWN'S IRON BITTERS is invaluable. Try it.

Be sure and get the Genuine.

Attention, Boiler-makers and Engineers!

Just Out! The Best Work of its Class Published!!

The Theoretical and Practical Boiler-maker.

By SAMUEL NICHOLS, Experienced Boiler-maker. Embarrassed with details of Geometry and Orthographic Projection as applied to Boilermaking; also to make, draw, design, and set out all kinds of Templet Work, as Ellipses, Cones, Truncated Cones, Oblique Cones, Frustums of Cones, Chimney Bottoms, Cylinders, Cylinder and Cone, Cylinder and Sphere, Cylinder connected with Curved Tube, Cylinder and Angular Tube, Cylinder with Spiral Staircase, Hip Roof and Cylinders, Tubes, Angular Tubes, T Tubes, Taper Tubes, Curved Tubes, Quadrant Tubes, Downtake Tubes, Flues, Spheres, Domes, etc., of every kind. Illustrated with 74 diagrams, including a full solution of all the problems relating to Boilermaking. The Cylinder, its sections, penetration, and development; Welding and Construction, Drilling, Punching, Riveting, Single and Double Riveted Lap and Butt Joints, with Single and Double Strips. Diameter, Spacing, Strength, and Pitch of Rivets; Strength and Pitch of Stays. On Locomotive, Marine, Cylindrical, and Egg-ended Boilers; Power of Boilers; Heating Surface of Boiler Tubes in square feet; the Lever Safety-Valve; the Cylinder, the Sphere, Area of Fire Grates; Quantity of Steam required for an Engine; Flat Surfaces, Boiler Explosions; Practical Notes on Steam; Properties of Saturated Steam; Proportion of Boilers; Bursting pressure of lap-jointed Wrought Iron Cylindrical Boilers; Collapsing pressure of Wrought Iron Cylindrical Tubes of varying thicknesses. Practical Rules, Instruction, and Memoranda for Boilermakers; Material for Boiler Construction; Welding, Strength, and Dimensions of Wrought Iron Boiler-plates and Iron Bars; Strength of Steel Plates, treatment of do.; Strength of Plates at different temperatures; Strength of Ropes and Chains; Properties of Metals; Weight of Wrought Iron Cylinders per lineal foot of any given diameter and thickness; Angle-iron Hoops; Diam., Cir., and Areas of Circles, with detailed calculations relating to Boiler Construction; to determine thickness of Boiler Heads, Cylinder Covers, etc. Mensuration as applied to Boiler-making; Fuel Valves, Construction of Fuel, Evaporation of Water; Setting Boilers, Incurstion, Boiler Scale Preventives, 35 kinds; Decimal equivalents, Weight of Water; Expansion of Water; Squares, Cubes, and Roots; Fusing Points of Metals; Conducing Powers of Metals; Useful Definitions. Reference Tables (83 pages) for Boiler-makers, Engineers, Smiths, etc. 1 vol. 12mo, extra cloth. Mailed post free to any address on receipt of \$2.50. Sent for 128 pages illustrated Catalogue of 3000 Standard Books on every subject. Agents wanted. National Book Company, 73 Beekman Street, New York.

BERRY & PLACE MACHINE CO., Sole Agents,

No. 8 CALIFORNIA STREET, S. F.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

F. A. HUNTINGTON,

No. 45 Fremont Street. - - San Francisco, Cal.

**PATTEN'S CONCENTRATOR.**

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

**SHINGLE MACHINE.**

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

THE BUCK THORN BARBED FENCE (One Piece Solid Steel.)

\$1,000 CHALLENGE!**THE FRUE ORE CONCENTRATOR,**

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machines infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machines, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Exhaust Fans and Pressure Blowers.

About a year ago, Wright D. Smith, superintendent of a planing mill at Detroit, devised a new form of fan, which speedily attracted the attention of mill men by its wonderful performances. The planing mill of M. C. Huyett & Co. was recognized as the model mill of Michigan, when erected in 1881. In it one of these fans of 400 square inch inlet has been in constant use, driven by a four-inch belt on a seven-inch pulley. It blows the surplus shavings 600 feet under five railroad tracks, and up into a storage and sales house.

Fig. 1 of the accompanying engravings shows the fan with one side removed. It will be seen that the radical improvements spoken of are two in number, and consist of a peculiar arrangement of the fan-blades, and the use of double cut-off, or discharge points. The construction of the case, or shell, is entirely different from anything heretofore made; it can be taken apart—both wheels, shaft and pulley removed in five minutes by any one who can handle a monkey-wrench. The spiders, or arms to which the fan-blades are attached, are set so that those next to the inlet side of the fan travel ahead of their fellow, giving a peculiar "skew" to the fan-blades, which arrangement forms one of the especial features of the fan, and is the subject of a special claim in the inventor's patent. The advantages of the double cut-off are as follows: The material passing into the fan, between the center and left side of the inlet, takes an upward direction, and the compression of the blades is cut off at their right hand upper corner of the inlet box, the material and air passing out of the fan case under the partition shown in the figure where the side is removed. Material passing in between the center and right side of the inlet takes a downward direction, and the compression is cut off at the left lower corner of the inlet, the compression being absolutely cut off twice in each revolution of the wheel. In this manner it is perfectly feasible, by suitably arranging the pipes, to blow sawdust and shavings through the same fan, and send them in different directions, unmixed, a feat that would of course be impossible of accomplishment with one cut-off and outlet. The blast wheel is about one third less in width and diameter than any other fan of the same capacity. For example: A fan of 200 inches inlet and 234 inches discharge, has a blast wheel 15½ inches in diameter and 8 inches wide, with a steel shaft 1½ inches in diameter by 30 inches in length.

The makers declare their ability to substantiate the extraordinary claim that the Smith fan requires only one half the power to operate it needed by any other machine of the same capacity, and assert that it commends itself to users upon the following grounds:

First—It has a direct suction inlet, requiring no elbow to connect it with the main suction pipe, thereby maintaining a powerful and unobstructed suction.

Second—It is two fans propelled by one pulley and a shaft, each separate and distinct from the other, and they may be piped to the exhaust room in one or two pipes, as may be desired.

Third—It is driven with one belt and pulley, from the center of the shaft, with the boxes close on either side the pulley, thus giving the greatest strength to all the running parts and avoiding the spring and vibration common to

other fans with long shafts and overhanging pulleys.

Fourth—The two cut-off points, each discharging a volume of air one third the diameter and the whole width of the fan, gives an outlet of more than two thirds the diameter and the whole of the width.

The economical point, or location of the cut-off, is recognized by experts to be one third the diameter of the wheel. Ordinary fans have but one cut-off, consequently, after the blade

Manufacture of Borax.

In manufacturing the borax of commerce at the great borate deposits on this coast considerable expense is entailed in the purchase and transportation of the ordinary hydrated sulphuric acid. In the manufacture of sulphuric acid special preparation and apparatus are necessary. It is well known that to make acid upon a small scale is very unprofitable, and to engage in its manufacture with sure prospects

to set free the boracic acid more rapidly and effectively, by the employment of a strong reagent, and to cheapen the cost of operation by providing a means for making this reagent directly and in close connection with the substance to be acted upon, whereby the necessity of two operations—to-wit, the separate and expensive manufacture of the sulphuric acid, and its transportation as such to the field of operation—is avoided. The process consists in a means of forming nitrous and sulphurous vapors, and admitting air thereto, and in a means for forcing said vapors into a tank containing a suspension or solution of the borate.

A tank is provided for the solution, and an ordinary furnace is used for containing sulphur to undergo combustion. In this furnace is a pot containing any suitable nitrate. The furnace has a front aperture with a sliding door, so as to admit more or less air. A pipe connects the furnace with the tank, said pipe extending down in the tank nearly to its bottom. A steam boiler is provided, from which is a pipe extending into the other pipe, which connects the furnace and tank so that pressure of steam will act as an injector and carry the furnace vapors into the borate solution in the tank.

The process is as follows: In the tank is placed water and the borate introduced. If borate of soda, a solution is formed; if borate of lime or magnesia, they are held in suspension. In the furnace is placed sulphur, and it is ignited. The pot rests over the sulphur and contains any suitable nitrate—such as nitrate of soda—which is commonly used in the manufacture of sulphuric acid. In order to start and assist the operation, Mr. Robertson places in the pot with the nitrate a small quantity of hydrated sulphuric acid. In this furnace are formed, as is well known, the nascent gases of sulphuric acid—namely, the nitrous and sulphurous vapors—which, together with the air drawn in through the front of the aperture, contrive to produce the result. The steam from the boiler passing through the pipe acts as an injector, and forces or carries with it these vapors through the furnace pipe into the borate solution or suspension in the tank.

The effect of this is that sulphuric acid is formed and introduced directly to the solution. It takes up the soda, lime, magnesia, or whatever may be the base of the borate, and precipitate it as a sulphate. The boracic acid (B_2O_3) is set free, and the solution may be drawn off, where it crystallizes in a free state in the proper crystallizing pans. The effect of the acid in the borate solution is the same whether this latter be cold or hot—that is, the reaction takes place, and the boracic acid is liberated, so that at the beginning of the operation, when the solution is cold, the operation is taking place; but before the process is complete the solution warms up under the steam, so that when ready to be drawn off it is hot enough to provide for the proper crystallization of the boracic acid. Thus no time is lost and the means will conduce to the end. This treatment with sulphuric acid formed directly and in connection with the borate solution, the inventor deems preferable to the treatment with sulphurous acid gas (SO_2) because he attains a stronger and more effective reagent with as little trouble. The great advantage possessed by the process over that in which the hydrated sulphuric acid of commerce is used is that it is more economical both in trouble and expense. Of course Mr. Robertson is aware that heretofore borates in solution have been treated with sulphurous acid, and does not broadly claim this, but confines himself to the details described.

HUYETT & SMITH'S EXHAUST FANS AND PRESSURE BLOWERS.

has passed this point, it meets resistance in compressed air until it has passed entirely around its circuit.

In less than a year after the introduction of the machine, the manufacturers were compelled to erect extensive machine shops to enable them to supply the demand, and their fans have been sent all over the country. Further information concerning them may be obtained by addressing the Berry & Place Machine Co., 8 California street, in this city.

CAPT. KANS maintains that there is danger of the bulk of the water of the Mississippi river finding its way to the gulf through the Atchafalaya outlet, and, in that event, New Orleans would be left on the banks of a dead lagoon.

of success an expensive plant is necessary. For this reason it is made in but few localities, and it therefore becomes necessary to purchase it and undertake the extreme risk and high rates of transportation to the place or places where the borates are usually found. Wm. B. Robertson, Jr., of this city, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a simple and inexpensive means of forming its nascent gases directly and upon the spot; and also a process for treating the borates with them. The process is such as to avoid expense; and one advantage is that the waste is avoided attending the employment of the sulphuric acid of commerce when poured directly into the borate solution.

The object of the process is twofold, namely:

The New Tariff on Metals.

Iron ore, including manganiferous iron ore, also the dross or residuum from burnt pyrites, seventy-five cents per ton. Sulphur ore, as pyrites or sulphuret of iron in its natural state, containing not more than three and one half per centum of copper, seventy-five cents per ton: Provided, that ore containing more than two per centum of copper shall pay, in addition thereto, two and one half cents per pound for the copper contained therein.

Iron in pigs, iron kentledge, spiegeleisen, wrought and cast scrap iron, and cast steel, three tenths of one per cent per pound; but nothing shall be deemed scrap iron or scrap steel except waste or refuse iron or steel that has been in actual use, and is fit only to be remanufactured.

Iron railway bars, weighing more than twenty-five pounds to the yard, seven tenths of one cent per pound.

Steel railway bars and railway bars made in part of steel, weighing more than twenty-five pounds to the yard, seventeen dollars per ton.

Bar iron, rolled or hammered, comprising flats not less than one inch wide, nor less than three eighths of an inch thick, eight tenths of one cent per pound; comprising round iron not less than three fourths of one inch in diameter, and square iron not less than three fourths of one inch square, one cent per pound; comprising flats less than one inch wide, or less than three eighths of one inch thick; round iron less than three fourths of one inch and not less than seven sixteenths of one inch in diameter, and square iron less than three-fourths of one inch square, one and one tenth of one cent per pound: Provided, that all iron in slabs, blooms, loops, or other forms, less finished than iron in bars, and more advanced than pig iron, except castings, shall be rated as iron in bars, and pay duty accordingly; and none of the above iron shall pay a less rate of duty than thirty-five per centum ad valorem; Provided further, that all iron bars, blooms, billets, or sizes or shapes of any kind in the manufacture of which charcoal is used as fuel, shall be subject to a duty of twenty-two dollars per ton.

Iron or steel T rails, weighing not over twenty-five pounds to the yard, nine tenths of one cent per pound; iron or steel flat rails, punched, eight tenths of one cent per pound.

Round iron, in coils or rods, less than seven sixteenths of one inch in diameter, and bars or shapes of rolled iron not specially enumerated or provided for in this Act, one and two tenths of one cent per pound.

Boiler, or other plate iron, sheared or un-sheared, skelp iron, sheared or rolled in grooves, one and one fourth cents per pound; sheet iron, common or black, thinner than one inch and one half, and not thinner than number twenty wire gauge, one and one tenth of one cent per pound; thinner than number twenty wire gauge, and not thinner than number twenty-five wire gauge, one and two tenths of one cent per pound; thinner than number twenty-five wire gauge, and not thinner than number twenty-nine wire gauge, one and five tenths of one cent per pound; thinner than number twenty wire gauge, and all iron commercially known as common or black taggers' iron, whether put up in boxes or bundles or not, thirty per centum ad valorem; and provided, that on all such iron and steel sheets or plates aforesaid, excepting on what are known commercially as tin plates,terne plates, and taggers' tin, and hereafter provided for, when galvanized or coated with ink or spelter, or other metals, or any alloy of those metals, three fourths of one cent per pound additional.

Polished, planished or glanced sheet iron or sheet steel, by whatever name designated, two and one half cents per pound; *Provided*, That plate, or sheet iron, or taggers' iron, by whatever name designated, other than the polished, planished or glanced herein provided for, which has been pickled, or cleaned by acid, or by any other material or process, and which is cold rolled, shall pay one quarter cent per pound more duty than the corresponding gauges of common, or black sheet, or taggers' iron.

Iron or steel sheets, or plates, or taggers' iron, coated with tin or lead, or with a mixture of which these metals is a component part, by the dipping or any other process, and commercially known as tin plates, terne plates, and taggers' tin, one cent per pound; corrugated, or crimped sheet iron or steel, one and four tenths of one cent per pound.

Hoop, or band, or scroll, or other iron, eight inches or less in width, and not thinner than number ten wire gauge, one cent per pound; thinner than number ten wire gauge, and not thinner than number twenty wire gauge, one and two tenths of one cent per pound; thinner than number twenty wire gauge, one and four tenths of one cent per pound: *Provided*, that all articles not specially enumerated or provided for in this Act, whether wholly or partly manufactured, made from sheet, plate, hoop, band, or scroll iron herein provided for, or of which such sheet, plate, hoop, band, or scroll iron shall be the material of chief value, shall pay one fourth of one cent per pound more duty than that imposed on the iron on which they are made, or which shall be such material of chief value.

Iron and steel cotton ties, or hoops for baling purposes, not thinner than number twenty wire gauge, thirty-five per centum ad valorem.

Cast iron pipe of every description, one cent per pound.

Cast iron vessels, plates, stove plates, and irons, sadirons, tailors' irons, hatters' irons, and

castings of iron, not specially enumerated or provided for in this Act, one and one quarter of one cent per pound.

Cut nails and spikes of iron or steel, one and one quarter of one cent per pound.

Cut tacks, brads, or sprigs, not exceeding sixteen ounces to the thousand, two and one half cents per thousand: exceeding sixteen ounces to the thousand, three cents per pound.

Iron or steel railway fish plates, or splice bars, one and one fourth of one cent per pound.

Malleable iron castings, not especially enumerated or provided for in this Act, two cents per pound.

Wrought iron or steel spikes, nuts or washers, and horse, mule or ox shoes, two cents per pound.

Anvils, anchors, or parts thereof, mill-stones and mill-crank of wrought iron, and wrought iron, and wrought iron for ships, and forgings of iron and steel for vessels, steam engines and locomotives, or parts thereof, weighing each twenty-five pounds or more, two cents per pound.

Iron or steel rivets, bolts, with or without threads or nuts, or bolt blanks, and finished hinges or hinge blanks, two and one half of one cent per pound.

Iron or steel blacksmiths' hammers and sledges, track tools, wedges and crowbars, two and one half of one cent per pound.

Iron or steel axles, parts thereof, axle bars, axle blanks, or forgings for axles, without reference to the stage or state of manufacture, two and one half of one cent per pound.

Forging of iron and steel or forged iron, of whatever shape or in whatever stage of manufacture, not specially enumerated or provided for in this Act, two and one half cents per pound.

Horseshoe nails, hob-nails and wire nails, and all other wrought iron or steel nails, not specially enumerated or provided for in this Act, four cents per pound.

Boiler tubes, or flues, or stays, of wrought iron or steel, three cents per pound.

Other wrought iron or steel tubes or pipes, two and one quarter cents per pound.

Chain or chains of all kinds, made of iron or steel, not less than three fourths of one inch in diameter, one and three quarters cents per pound; less than three fourths of an inch and not less than three eighths of an inch in diameter, two cents per pound; less than three eighths of one inch in diameter, two and one half cents per pound.

Crosscut saws, eight cents per linear foot.

Mill, pit and drag saws, not over nine inches wide, ten cents per linear foot; over nine inches wide, fifteen cents per linear foot.

Circular saws, thirty cents per ad valorem.

Hand, back, and all other saws, not specially enumerated or provided for in this Act, forty per centum ad valorem.

Files, file blanks, rasps, and floats of all cuts and kinds, four inches in length and under, thirty-five cents per dozen; over four inches in length and under nine inches, seventy-five cents per dozen; nine inches in length and under fourteen inches, one dollar and fifty cents per dozen, fourteen inches in length and over, two dollars and fifty cents per dozen.

Steel ingots, cogged ingots, blooms, and slabs, by whatever process made, die blocks or blanks, billets and bars, bands, hoops, strips, and sheets of all gauges and widths, plates of all thicknesses and widths, steamer, crank, and other shafts, wrist or crank pins, connecting rods and piston rods, pressed, sheared, or stamped shapes, or blanks of sheet or plate steel, or combination of steel and iron, punched or not punched, hammerblonds or swaged steel, gun molds not in bars, alloys used as substitutes for steel tools, all descriptions and shapes of dry sand loom, or iron molded steel castings, all of the above classes of steel not otherwise specially provided for in this Act valued at four cents a pound or less, forty-five per centum ad valorem; above four cents a pound and not above seven cents per pound, two cents per pound; valued at seven cents and not above ten cents per pound, two and three fourths cents per pound; valued at above ten cents per pound, three and one fourth cents per pound. *Provided*, that on iron or steel bars, rods, strips or steel sheets, of whatever shape, and on all iron or steel bars of irregular shape or section, cold rolled, cold hammered, or polished in any way in addition to the ordinary process of hot rolling or hammering, there shall be paid one fourth cent per pound in addition to the rates provided in this Act, and on steel circular saw plates there shall be paid one cent per pound in addition to the rates provided for in this Act.

Iron or steel beams, girders, joists, angles, channels, car-truck channels, tees, columns and posts, or parts or sections of columns or posts, deck and bulb beams, and building forms, together with all other structural shapes of iron or steel, one and one fourth of one cent per pound.

Steel wheels, and steel wired wheels for railway purposes, whether wholly or partly manufactured, two and one half of one cent per pound; iron or steel ingots, cogged ingots, blooms, or blanks for the same, without regard to the degree of manufacture, two cents per pound.

Iron or steel rivet, screw, nail and fence wire rods, round, in coils and loops, not lighter than number twenty wire gauge, valued at three and one half cents or less per pound, six tenths of one cent per pound. Iron or steel, flat, with longitudinal ribs, for the manu-

facture of fencing, six tenths of one cent per pound.

Screws, commonly called wood screws, two inches or over in length, six cents per pound; one inch, and less than two inches in length, eight cents per pound; over one half inch and less than one inch in length, ten cents per pound; one half inch and less in length, twelve cents per pound.

Iron or steel wire, smaller than number five, and not smaller than number ten wire gauge, one and one half cents per pound; smaller than number ten, and not smaller than number sixteen wire gauge, two cents per pound; smaller than number sixteen, and not smaller than number twenty-six wire gauge, two and one half cents per pound; smaller than number twenty-six wire gauge, three cents per pound.

Provided, That iron or steel wire covered with cotton, silk, or other material, and wire commonly known as crinoline, corset and hat wire, shall pay four cents per pound in addition to the foregoing rates. And provided further, That no article made from iron or steel wire, or of which iron or steel wire is a component part of chief value, shall bear a less rate of duty than the iron or steel wire from which it is made, either wholly or in part; and provided further, That iron or steel wire cloths, and iron or steel wire nettings, made in meshes, or any form, shall pay a duty equal in amount to that imposed on iron or steel wire of the same gauge, and two cents per pound in addition thereto. There shall be paid on galvanized iron or steel wire (except fence wire), one half of one cent per pound in addition to the rate imposed on the wire of which it is made. On iron wire rope and wire strand, one cent per pound in addition to the rates imposed on the wire of which it is made. On steel wire rope and wire strand, two cents per pound in addition to the rates imposed on the wire of which it is made.

Steel not specially enumerated or provided for in this Act, forty-five per centum ad valorem. *Provided*, That all metal produced from iron or its ores, which is cast and malleable, of whatever description or form, without regard to the percentage of carbon contained therein, whether produced by cementation, or converted, cast, or made from iron or its ores, by the crucible, Bessemer, pneumatic, Thomas-Gilchrist, basic, Siemens-Martin, or open-hearth process, or by the equivalent of either, or by the combination of two or more of the processes, or their equivalents, or by any fusion or other process which produces from iron or its ores a metal either granular or fibrous in structure, which is cast or malleable, excepting what is known as malleable iron castings, shall be classed and denominated as steel.

No allowance or reduction of duties for partial loss or damage, in consequence of rust or of discoloration, shall be made upon any description of iron or steel, or upon any partly manufactured article of iron or steel, or upon any manufacture of iron and steel.

Argentine, albata or German silver, manufactured, twenty-five per centum ad valorem.

Copper, imported in the form of ores, two and one half cents on each pound of fine copper contained therein; regulus of and black or coarse copper cement, three and one half cents on each pound of fine copper contained therein; old copper fit only for re-manufacture, chippings from new copper, and all composition metal of which copper is a component material of chief value not specially enumerated or provided for in this Act, three cents per pound; copper in plates, bars, ingots, Chili or other pigs, and in other forms not manufactured, or enumerated in this Act, four cents per pound; in rolled plates, called brazier's copper, sheets, rods, pipes and copper bottoms, and all manufactures of copper, or of which copper shall be a component of chief value, not specially enumerated or provided for in this Act, thirty-five per centum ad valorem.

Brass, in bars or pig, old brass, and clippings from brass or Dutch metal, one and one half cents per pound.

Lead ore, and lead dross, one and one half cents per pound.

Lead, in pigs and bars, molten and old refused lead run into blocks and bars, and old scrap lead, fit only to be remanufactured, two cents per pound.

Lead in sheets, pipes or shot, three cents per pound.

Nickel in ore, matte, or other crude form, not ready for consumption in the arts, fifteen cents per pound on the nickel contained therein.

Nickel, nickel oxides, alloy of any kind in which nickel is the element of chief value, fifteen cents per pound.

Zinc, spelter, or tutenag, in blocks or pigs, and old, worn-out zinc, fit only to be remanufactured, one and one half cents per pound; zinc, spelter, or tutenag in sheets, two and one half cents per pound.

Sheeting, or yellow metal, not wholly of copper, nor wholly nor in part of iron, mangle, in sheets, forty-eight inches long and fourteen inches wide, and weighing from fourteen to thirty-four ounces per square foot, thirty-five per centum ad valorem.

Antimony as a regulus or metal, ten per centum ad valorem.

Bronze powder, fifteen per centum ad valorem.

Cutlery not specially provided for in this Act, thirty-five per centum ad valorem.

Dutch or bronze metal, in leaf, ten per centum ad valorem.

Steel plates, engraved, stereotyped plates, and new type, twenty-five per centum ad valorem.

Gold leaf, one dollar and fifty cents per package of 500 leaves.

Hollow ware, coated, glazed or tinned three cents per pound.

Muskets, rifles and other firearms, not specially enumerated or provided for in this Act, twenty-five per centum ad valorem.

All sporting breech-loading shot-guns, and pistols of all kinds, thirty-five per centum ad valorem.

Forged shot-gun barrels, rough-bored, ten per centum ad valorem.

Needles, for knitting or sewing machines, thirty-five per centum ad valorem.

Needles, sewing, darning, knitting, and all others not specially enumerated or provided for in this Act, twenty-five per centum ad valorem.

Pen-knives, pocket knives, and all knives and razors, fifty per centum ad valorem; swords, sword-blades, and side-arms, thirty-five per centum ad valorem.

Pens, metallic, twelve cents per gross; pen-holder tips and pen-holders, or parts thereof, thirty per centum ad valorem.

Pins, solid heads or other, thirty per centum ad valorem.

Britannia ware, and plated and gilt articles and wares of all kinds, thirty-five per centum ad valorem.

Quicksilver, ten per centum ad valorem.

Silver lead, seventy-five cents per package of five hundred leaves.

Type metal, twenty per centum ad valorem.

Chromate of iron, or chromic ore, fifteen per centum ad valorem.

Mineral substances in a crude state, and metals unwrought, not specially enumerated or provided for in this Act, twenty per centum ad valorem.

Manufactures, articles or wares not specially enumerated or provided for in this Act, composed wholly or in part of iron, steel, copper, lead, nickel, pewter, tin, zinc, gold, silver, platinum, or any other metal, and whether partly or wholly manufactured, forty-five per centum ad valorem.

A Great Ditch Enterprise.

The New Ditch of the South Yuba Co.—Reservoir Building.

A reporter of the Nevada *Transcript* has been along the line of the new ditch, and has this to say about it:

J. E. Brown and a *Transcript* reporter went on a trip of inspection over the lower portion of the new Town Talk ditch. It is a model piece of work from one end to another, the grades being faultless and all the work, both trenching and fluming, of the very best kind. It is probably the most substantially constructed canal owned by the South Yuba Company, and has a capacity of 2,000 inches. The details of the work have been carried out under the supervision of John Spaulding, the company's very efficient Superintendent. By the building of this ditch thousands of acres of rich land, beginning on the slopes of Banner Mountain and extending down into the Allison Ranch part of the county, much of which has heretofore been practically valueless because of lack of water, will from this time forward be highly productive in fruit, vegetables, corn and hay. The line of the ditch is upon the summit of the ridge most of the way, and along both sides the ranches will be benefited beyond measure. The principal object in building the ditch was, however, to supply the demand in the portions of this and Grass Valley townships lying in proximity to its course for a cheap and reliable motive power for mining and prospecting purposes, as has been mentioned in these columns heretofore. It will advance the mining, agricultural and horticultural prosperity of this part of the county more materially than any other step that could have been devised, and will begin at once to redound to the profit of the projectors.

At Pingree's ranch the company now has fifteen teams and eighty men at work building its main distributing reservoir for Grass Valley district. It is to have an area of seven acres and a depth of twenty-one feet. The site selected is a depression on the backbone of the ridge, at the lowest side of which is being constructed an earthen embankment seventy feet wide at its base, twenty-one feet high, sloping to a width of twelve feet on top, and about 700 feet in length. The work at this reservoir is being done under the supervision of Wm. Mcservey, who is to have charge of that section of the line when it is completed. The lake is to be stocked with fish, a boat will be launched, and the surroundings are naturally very picturesque. It is some distance from any regular line of travel, and will by another year prove a delightful summer resort.

A mile nearer to Grass Valley is being made another and similar reservoir for the especial use of the Idaho Mining Company. From this reservoir to the mine the water will be conducted by iron pipes, and after being used for power at that mine, will be allowed to flow on down towards Allison Ranch where it will be disposed of for irrigation purposes.

THE Mountain Chief property, located near the Ontario at Park City, is now involved in a contest in the courts for the purpose of determining title.

A New strike is reported in the Apex mine, Park City. It is reported the body of ore is large and of good quality.

TRAVEL is beginning to set in toward Wood River at a lively rate.

MECHANICAL PROGRESS.

Thoughts on Belts.

A noted feature in many manufactories is unnecessary tension of belts, which not only shortens the life of them, but absorbs considerable power that should be utilized in doing useful work; and the resultant of the power wasted is the heating of journals and melting of habbitt metal. Moreover, no shaft can remain long in line where belts are run needlessly tight, and the extra coal burned is of no little importance, besides wear and tear of the plant, and delays caused by broken belts, etc.

It will be much more effectual and satisfactory to decrease the tension of the belts and increase the diameters of the pulleys, or width of belts, rather than run them too tight. More than one instance could be chronicled where as high as fifteen per cent. of the power used was consumed in overcoming friction caused by tight belts.

The driven pulley on line shafts should be placed as near the center of the work as possible. When it is not convenient to locate the driven pulley at or near the center of the work, it is desirable in all cases to have bearings both sides of the pulley, and in close proximity to it, to receive the pull of the belt. Narrow belts are more usually run extra tight than wide ones, owing to the extra duty required of them, in proportion to their strength, than larger ones.

The experiments of both scientific and practical men differ so widely, and the results are so unsatisfactory that an ordinary individual can gain but little knowledge from them which would be of utility, consequently he has to use his judgment, and depend upon common sense and the circumstances existing, in producing details and dimensions to meet his requirements. There are so many circumstances and conditions that influence the driving power, and satisfactory working of the belts that no infallible rules can be laid down, nor advice given, which would give the same results or efficiency in all cases. Leather belts should not be used in damp places, but if used should be kept well oiled, and the laps should be sewed instead of riveted to give the best results.

Increasing the tension of belts by the use of tighteners (so-called) should be avoided if possible, as they conduce to ruin the belt, and require care, oil, power and repairs.—*Mechanical Engineer.*

ECONOMICAL GAS GENERATORS AND ENGINES.

The power for the new gas engine works of Messrs. Crossley Bros., Limited, (Eng.) is to be obtained from gas engines driven with generator gas made by the Dowson process. Nearly all the plant for 150-horse power has been put down, consisting of three producers connected with three scrubbers for washing the gas, and a holder for compensating the supply and regulating the pressure. Messrs. Crossley have had a 30-horse power engine working regularly with this gas during about two months, under test conditions. It has been found that the generators took forty-five minutes in firing up, and afterward the fuel consumption per 1,000 cubic feet of gas passed into the holder was 13.2 pounds. The *Journal of Gas Lighting* says that the consumption of the engine was at the rate of 109 cubic feet per indicated horse power, representing a fuel consumption of 1.4 pounds per horse power per hour. The coal used is small sized anthracite, costing 3s. 6d. per ton in truck at the pit. The wages for the fireman for the gas generators are about the same as for a set of steam boilers. Thus the economy of the system consists chiefly in the low rate of fuel consumption. This consideration is important, in connection with the fact that the engines are small; for it will enable different lines of shafting to be driven by separate engines as economically with regard to fuel as by a single large engine of the best construction. Any department may therefore be kept at work independently of others. Against this advantage must be set off, in the case of manufacturers who have to purchase their gas engines, the high price of these machines and the added cost of the gas producing plant.—*Scientific American.*

SOME CAUSES OF BOILER CORROSION.—Herr Keil names two causes of the internal and external corrosion of boiler plates, which, he observes, have hitherto been but little studied. These are the chemical composition of the metal composing the plates and the influence of the vibrations of temperature. A highly carburized plate, approaching nearly to steel, will become oxidized less readily than one containing very little carbon. On the other hand, phosphorus, sulphur, manganese, silicon, and magnesium favor oxidation, and consequently corrosion; and, as these substances are not uniformly distributed over the metal, some parts of a plate are attacked in preference to others. With regard to the second cause, certain portions of the boiler are, more than others, subject to rapid changes of temperature. Thus, the fluctuations of the water level often cause a portion of the plates to be left unprotected by the water on one side, while on the other it is always exposed to the action of the fire. Consequently corrosions are often noticed near the water line which are not met with either above or below it. The same thing is observed along a seam of rivets where there are two, and sometimes three, thicknesses of plate, which form an obstacle to the uniform absorption of heat.

A NEW SYSTEM OF MELTING IRON.—A new system of melting iron, and at the same time incorporating in it scrap, wrought iron, etc., has been invented by Herr Bruegger, a well known engineer, who has built one furnace at the Michelbacher Huette, at Michelbach, Prussia, and another at the works of Julius Meyer & Co., at Nordon. The cupola is supplied with blast through two sets of tuyeres, one above the other, there being eighteen in each set. The tuyeres or ports, which have the form of a vertical slot, are directly connected with a circular tyre ring. The particular feature of the cupola is that the bottom is a slightly inverted arch, which is pierced by two openings through which both blasts, or rather imperfectly consumed gases of combustion, and the fluid iron can flow. Below is a small chamber in which the iron collects. It is heated by the gases forced downward from the cupola above, which are supplied with the necessary air for combustion by a special tyre leading from the main blast pipe. The chamber at the same time serves for preheating scrap, etc., which need only be pushed into the bath for dissolving it. Of course it is well known that considerable quantities of scrap can be used by directly charging any ordinary cupola; but it is claimed that in this case there are economy of fuel and a greater facility for making sharp, strong castings and a purer metal. The best iron for this purpose is said to be inferior pig, like No. 3 Middleborough, holding considerable silicon and little manganese. To it, from forty to fifty per cent. of scraps, etc., may be added.

PHOSPHOR BRONZE FOR TELEGRAPH WIRES.

The substitution of phosphor bronze for iron in telegraph wires has already been alluded to in these columns, and we now refer to the following from *Cotton, Wool and Iron*, of Boston: The Phosphor Bronze Smelting Company, of Philadelphia, Pa., have been carefully experimenting for two years and over, upon a phosphor bronze telephone wire. Recent improvements in this seem to give it a front rank in the various kinds of material offered for this purpose. It does not tend to kink, will lie straight when unwound from the reel, and can be put up and handled with the same facility as other wire. Its resistance to corrosion is such that small wires, even numbers sixteen to eighteen, can be used without danger of rapid deterioration from the corrosive action of smoke, acid fumes, dampness, and the general obstacles. Its tensile strength is high, or about four times its weight per mile. It is very light weight, which fits it for long spans, and so small as to be hardly visible, and therefore free from the objection of the "unsightly telegraph wires." Its resistance is about one half that of iron wire of equal weight. Stubb's gauge, 16.065 of an inch in diameter, 66 pounds per mile, breaking strain 275 pounds. The calculated resistance 50 ohms per mile. These parties are now ready to fill orders for this in connection with their varied manufactures.

THE LARGEST WOOD PLANER.—Ship timbers require the services of large machines to handle them properly. A Bath, Maine, ship yard contains a planer supposed to be the largest in the world. It will work a piece of timber sixty-six feet long, five feet wide and two and one half feet thick. The keel comes from this machine perfectly true, ready for laying. The same yard contains a big beveling saw, which turns out timber sawed to any desired angle from horizontal. Curved timber and ship-knees can be worked true to the line by it. The same engine that runs these machines also drives a bolt cutter which bites off round iron up to two inches in diameter, a large and small circular saw, a machine for making tree nails, a band saw, planer, molding machine, and a plug and wedge machine. The exhaust steam is used for steaming timber preparatory to bending it.

THE STEAM ENGINE.—Taking the best types of engines of to-day as a starting point, we must depart in the following directions: We do not particularly need to increase the efficiency of the boiler as an evaporator, but we must increase its ability to withstand pressure without increasing its cost. We must decrease the friction of the engine and of the machinery of transmission to the point where the useful work is delivered. We must produce better vacuums in the condenser, and diminish its cost. We must diminish the cost of the engine. We must diminish the cost of the attendance on engines, boilers and machinery, and of lubrication. We must increase the durability of engines, boilers and machinery. Coal is too cheap even now to admit of increased economy of it at the cost of increased outlay for plant and attendance.

STEAM BOILER ACCIDENTS.—According to the annual report of the Hartford Steam Boiler Inspection and Insurance Company, there were 50 boiler explosions last year in sawmills and wood-working establishments generally. This is more than twice the number occurring in any other line of steam-using manufactures.

IMPROVEMENT IN SAWMILL MACHINERY.—A cotemporary says the great improvements in sawmills and machinery within the past few years give facilities for economizing in the production of timber, which people 20 or 30 years ago did not possess—not even in their dreams—and which make an incalculable difference in the amount of material and labor saved.

SCIENTIFIC PROGRESS.

The Exciting Property of Oats.

Experiments have been recently made by M. Sanson with a view to settling the question whether oats have or have not the excitant property that has been attributed to them. The nervous and muscular excitability of horses was carefully observed with the aid of graduated electrical apparatus before and after they had eaten a given quantity of oats, or received a little of a certain principle which M. Sanson succeeded in isolating from oats. The chief results of the inquiry are as follows:—The pericarp of the fruit of oats contains a substance soluble in alcohol and capable of exciting the motor cells of the nervous system. This substance is not (as some have thought) vanillin, or the odorous principle of vanilla, nor at all like it. It is a nitrogenized matter, which seems to belong to the group of alkaloids; is uncrystallizable, finely granular, and brown in mass. The author calls it "avenine." All varieties of cultivated oats seem to elaborate it, but they do so in very different degrees. The elaborated substance is the same in all varieties. The differences in quantity depend not only on the variety of the plant, but also on the places of cultivation. Oats of the white variety have much less than those of the dark, but for some of the former, in Sweden, the difference is small; while for others, in Russia, it is considerable. Under 0.9 of the excitant principles per cent. of air-dried oats, the dose is insufficient to certainly affect the excitability of horses, but above this proportion the excitant action is certain. While some light-colored oats certainly have considerable excitant power, some dark oats have little. Determination of the amount of the principle present is the only basis of appreciation, though (as already stated) white oats are likely to be less exciting than dark. Crusting or grinding the grain weakens considerably the excitant property, probably by altering the substance to which it is due; the excitant action is more prompt, but much less strong and durable. The action, which is immediate and more intense with the isolated principle, does not appear till some minutes after the eating of the oats; in both cases it increases to a certain point, then diminishes and disappears. The total duration of the effect is stated to be an hour per kilogramme of oats ingested.

THE NEW ELECTRIC UNITS.—The late Electrical Congress decided to make use of the centimeter, gramme and second in all electrical measurements. They decided to retain the old units of measurement—that is, the "ohm," as the unit of resistance, and the "volt" for the unit of electromotive force. They added the following new units: The "ampere," which is to represent the intensity of the current produced by one "volt," with the resistance of an "ohm;" the "coulomb" is to signify the quantity of electricity given by an "ampere" in one second; the "farad" indicates the capacity of the condenser, which, laden with a "volt" holds one "coulomb" of electricity. The old term "weber" is abandoned. Dr. Siemens, in his presidential address before the British Association meeting last summer, urged the retention of the "weber" as the unit of magnetic quantity, and suggested the addition also of another unit to represent the power conveyed by a current of an "ampere" through the difference of potential of a "volt." This he proposes to call a "watt," in honor of the great mechanician, James Watt. A "watt" would, therefore, represent the rate of an "ampere" multiplied by a "volt." A horse power will be 746 "watts." Tabulating these units, we would have: 1. Weber, the unit of magnetic quantity; 2. Ohm, the unit of magnetic resistance; 3. Volt, the unit of electro-motive force; 4. Ampere, the unit of magnetic current; 5. Coulomb, the unit of magnetic quantity; 6. Farad, the unit of magnetic capacity; 7. Watt, the unit of magnetic power.

PRACTICAL USES OF LIQUEFIED CARBONIC ACID.—The *Berichte* of the German Chemical Society of Berlin lately contained an interesting communication from Prof. A. W. Hofmann, calling attention to the extensive use of liquid carbonic acid for various purposes. It appears that the production and sale of the liquefied gas is a regular business, carried on on the large scale. The gas is condensed and sold by Krupp, of the world famous iron works at Essen. It is used mainly to compress steel castings in closed molds. It is placed in wrought steel vessels which hold about 200 pounds of the liquefied gas. A pressure of 800 atmospheres (about 12,000 pounds) is obtained. In Krupp's works all the ice is manufactured with the aid of a machine which is kept constantly at work by compressed carbonic acid. One of the most interesting applications of the condensed gas has been recently made in Berlin in connection with fire engines. Each engine is supplied with a large vessel containing the liquefied gas. This is brought into use as a motor the instant the engine arrives at the place of the fire, and some of the gas is thrown with the water upon the flames. As soon as a sufficient steam pressure is obtained, the use of the carbonic acid is stopped.

How Flies Climb.

Herr H. Dewitz has communicated to the Berlin Society of Natural History some facts that bear very strongly against the generally received theory that flies adhere to perpendicular walls and ceilings by virtue of some sucking power in their feet. He asserts that the feet of flies can not possess the sucking property ascribed to them, for they are hard and destitute of muscles. The theory has long been contradicted by the experiments of Blackwell, who found that flies could climb the sides of a jar under the receiver of an air pump, where there was no atmospheric pressure, and who asserted that the power of adherence was due to a sticky matter secreted from the foot hairs of flies. This assertion was generally regarded as not proved, and the case has rested there. Dewitz reports that his investigations have shown that Blackwell was right. He has watched the exudation of the sticky matter from the feet of the flies by fastening one of the insects to the under side of a plate of glass and viewing it under the microscope. A perfectly clear liquid was seen to flow from the ends of the foot hairs and attach the foot to the glass. When the foot was lifted up to be put down in another place, the drops of the sticky matter were perceived to be left on the glass, in the exact places where the foot hairs had rested. The adhesive fluid appears to pass down through the hollow of the hair, and to be derived from glands which Leyding discovered in the folds of the foot in 1850. A similar adhesive matter appears to be possessed by bugs, by many larva, and probably by many insects that climb the stems and the undersides of the leaves of plants.

Obtaining Oxygen from the Air.

A method of obtaining oxygen from air for technical purposes has been devised by M. Margis, of Paris, the principle being that of diffusion under pressure. Atmospheric air being forced against a caoutchouc membrane by suction, a mixture of about forty per cent. oxygen and sixty per cent. nitrogen is obtained on the other side. A second membrane increases the proportion of oxygen to sixty per cent., that of nitrogen being reduced to forty per cent. A third gives eighty per cent. oxygen, and a fourth ninety-five per cent. The membranes are prepared by immersing taffeta in a solution containing bisulphide of carbon (or light petroleum ether), spirits of wine, ether and caoutchouc. When dry, the taffeta has a fine layer of caoutchouc. A bag of the taffeta, with a framework of rings of galvanized wire, is placed in a cylindrical iron vessel admitting air. It is connected by means of a strengthening caoutchouc tube with the suction apparatus, which is formed of a cylinder containing a series of conical cups with small spaces between. Steam is forced through these cups, and draws in the gas obtained from the first diffusion, passing on with it through a cooler, where the steam is condensed and the gas is separated for a second diffusion. This latter takes place in a similar apparatus, except that the space round the bag is provided with a tube passing down into water, so that the pressure can be regulated and the superfluous gas be let off. After the air has passed through four of these bags, the final gas is collected in a gasometer.

IMPROVEMENTS IN SECONDARY BATTERIES.—On the authority of Prof. Ayrton, a well-known English physicist, a great improvement in the secondary battery has been effected by the union of the patents of Faure, Sellen and Volkmar. As a consequence, the following performance of the batteries in lighting the Pullman train on the Brighton (Eng.) line is reported: This train was formerly lighted by eighteen incandescent lamps, supplied by seventy accumulators. With the new accumulators, it is now lighted with forty incandescent lamps, the current of which is supplied by thirty Faure-Sellen-Volkmar cells. Prof. Ayrton reports on the advantages gained by the above named combination, as follows: The old accumulators weighed 130 pounds in working order, and gave a current equivalent to one-horse power for three quarters of an hour; whereas the new accumulator weighs only about seventy-five pounds, and yields a current of one-horse power for an hour. The flannel, or felt, is dispensed with, and the plates are so arranged that a defective one can readily be removed and replaced.

EXPLOSIVE ALLOYS OF ZINC.—Iridosmium is projected into fused zinc, the mass kept in igneous fusion for six hours, and the cooled ingot is treated with hydrochloric acid, to remove the excess of zinc, etc. When the graphite-like residue, washed and dried at 212° Fah., is heated to 575° Fah., it instantly takes fire—almost explosively—giving off fumes of zinc and of osmic acid. This deflagration occurs also, in a vacuum, but naturally without the production of either zinc oxide or of osmic acid. At this last named temperature there is, therefore, a change of state, attended with great development of heat, which in the air occasions combustion. This phenomenon is so marked, that by its means one or two per cent of iridium may be detected in platinum. Ruthenium and rhodium produce similar effects.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

Mining Share Market.

There are no special points to note in the mining share market. There have been no fluctuations of any great moment. Everything

MORE universally recommended than any proprietary medicine made. A sure and reliable tonic. Brown's Iron Bitters.

The action of, or effects produced by, acid on corrosive matter in feed water greatly depends in the nature and amount of solid matter in the water. When a boiler is entirely free from scale acid water may be used in some cases for a considerable time without its injurious effects being noticed on the face of the plate, but it will work its way under braces, into seams, etc.,

Scale in steam boilers is one of the evils all steam-users experience, and many suppose it to be a necessary one. This is not, however, the case, for, with proper care and use of suitable substances, the evil is one that can be overcome. In this city boiler-users are particularly affected, especially where well water is used, as is the case in so many places. And this is one reason that people are willing to pay high prices to the water company instead of having their own wells, as the mineral water seems to make heavy deposits in the boilers. Impure water and incrustation cause great expense for fuel and repairs. There is no subject connected with the use of steam of more importance than that of the proper care of steam boilers. Upon this depends not only the safety of life and property, but in a very considerable degree the cost of producing the required power. The most eminent engineers of the country now agree that the majority of explosions occur from impaired strength of plates and rivets, caused by overheating and corrosion, in consequence of the formation of scale on the inner surface of the boiler. But few engineers comprehend the danger from this cause. When a boiler is clean, the action of the water when under working pressure of steam prevents any active corrosion, but when the tubes and inner surface of the plates are covered with scale and incrustation, corrosive action is carried on very rapidly, thinning and weakening the plates imperceptibly, but surely.

SIERRA.
GOLD DISTRICT.—*Mt. Messenger*, March 31.—Thirty-one pounds of gold dust was the result of recent clean-up in the Union gravel mine at Gibsonville. The Brady City M. Co. has located a portion

of the Boyce Ravine for tailings. The claim extends from the company's sawmill down to the ravine, about 2,800 ft.

SCALES DIGGING.—Poverty hill and Fair Play companies are not working steadily, as water is scarce. Cleveland does better. Union hill, a week ago, cleaned up \$1000, that, for the length of run, was doing very well.

TRINITY.

THE QUARTZ DISCOVERY.—Trinity Journal, March 31: Mr. James Moore came in from the East Fork of North Fork on Thursday afternoon and brought with him a piece of quartz from the location made by Will Day, which adjoins the original discovery of which mention was made last week. This piece weighs about 20 lbs, and the face of it is literally covered with fine particles of free gold, many of which are visible to the naked eye, while an ordinary magnifying glass reveals a bonanza of wealth. Mr. Moore says that on the other end of his location Mr. H. Smith has good prospects from an extension of the same lode which has now been uncovered, in all, some 1,600 ft. The ledge, he says, has a general direction of North and South, is from 18 to 24 inches thick, and pitches into the hill at an angle of about 45 degrees. The piece he brought in is on exhibition at Sam Hensley's Gem Saloon. Further developments are anxiously awaited, but present indications certainly point to an enormous bonanza.

Nevada.

WASHOE DISTRICT.

UNION CON.—Enterprise, March 31: East crosscut No. 1, on the same level, is showing well, but has yet a considerable distance to go before ore can be expected. Good progress is making in lateral drift No. 2. It is a vein formation of a very favorable appearance.

SIERRA NEVADA.—Good headway is being made in the joint Union Con, east crosscut on the 2900 level. The face is in vein material which exhibits no feature worthy of special note, except that it is growing much softer. This probably indicates that the drift is approaching the point where may be expected the ore cut in the joint Union Con, winze, at the time Senator Fair was in charge of the north end mines.

CON. VIRGINIA.—Better progress is now making in the southeast drift on the 250 level, as a cooling-off station has been made near the face.

YELLOW JACKET.—The yield of ore from the old levels at the Winters shaft still holds up to 75 tons per day. A good deal of prospecting is being done at several points, and some good bunches of ore are being encountered at one or two points. At a few places small streaks of ore that are quite rich have been found.

OPHIR.—The joint Mexican east crosscut on the 3100 level is being pushed ahead as rapidly as possible. It is still in black and barren porphyry.

HALE AND NORCROSS.—Crosscutting will probably be commenced on the 26 level in a few days.

SAVAGE.—The joint Hale and Norcross north drift on the 2600 level is being pushed ahead as rapidly as possible, and is in a very promising vein formation.

BRENT AND BELCHER.—The north drift on the 2500 level is again being pushed ahead to connect with the southeast drift of the Con. Virginia on the same level. The face is quite hot.

GOULD AND CURRY.—Fair progress is making in the west drift on the 2300 level, though the indications are that there is a considerable amount of water out toward the west wall. This it will be a difficult matter to wholly avoid.

UTAH.—The work of cleaning out the pipe drift in the Sierra Nevada ground is approaching completion.

CROWN POINT.—The yield of low-grade ore from the old upper levels continues about as heretofore, and the mills on the river are kept constantly employed.

ESMERALDA DISTRICT.

THE NEW ESMERALDA.—Esmeralda Herald, March 31: Work still continues on this mine, and if the samples shown us Wednesday are a fair average of the ore that is now being taken out, then the owners may yet become millionaires. The ledge in the New Esmeralda is very wide, and the ore differs from that of any other ledge in the district.

THE QUINCY.—Mr. Booker informs us that he has men at work on the Quincy mine, on Humboldt Hill, and that some very fine ore is being taken out. This mine lies alongside the Silver Lining, and is not over 100 yards from the Silver Hill mill, Gregory Flat, which will make the Quincy a very valuable property when developed. It is owned by Messrs. Hooker & Kimball.

GILLIS DISTRICT.

WORKED.—Walker Lake Bulletin, March 27: The Yellow Jacket mine, in Gillis district, is being steadily worked. Various other mines and prospects are having work done on them, and those interested are very hopeful as to the general result. A great deal of chloriding is carried on in the district, and those engaged in the business are doing well. Shipments of ore are even now occasionally made to San Francisco and other points.

JEFFERSON DISTRICT.

AT WORK.—Cor. Belmont Courier, April 4: The stamps of the Jefferson S. M. Co.'s mill were dropped Monday morning and have been going steadily ever since. The work of converting the ore into bullion has therefore been commenced in good earnest and the camp started into what bids fair to become a prosperous career. Much ore is ready at hand awaiting treatment with more being shipped from the mines daily. In fact everything is wearing a bright appearance and the Jeffersonians are consequently happy. The mines are rapidly being brought into condition for systematic working reflecting creditably upon the careful management. There is considerable excitement among our local prospectors because certain of their number brought in specimens of very rich silver ore, taken from mines in the vicinity, which they claim to have recently discovered. The ledge is said to be from two to three ft wide and the lowest assay reached \$235, some going high in the hundreds. The specimens are very beautiful containing horn silver and chloride in considerable quantities. As the owners keep remarkably close about their find it is difficult to ascertain full particulars.

PINTO DISTRICT.

NEW ENTERPRISE.—Enreka Sentinel, March 30: Yesterday the Trustees of the Berryman Tunnel and

M. Co. met at their office in the Foley-Rickard building, on Main street, and completed their organization, when the following officers were elected to serve for the present term: M. H. Joseph, President; H. K. Mitchell, Vice President; D. K. Sessions, Secretary, and Richard Berryman, Superintendent. This company has been organized for the purpose of developing six mining claims, each 1,500 feet long by 600 feet wide, upon Silverado Mountain in Pinto mining district. The enterprise is one of importance, as the development of such a property will assist in opening up one of the most valuable sections of mineral land in eastern Nevada. Work on the property will be commenced Monday morning, under the direction of Richard Berryman, assisted by L. F. Dibble. These gentlemen are first class miners, and have had very great experience generally. They are also very familiar with the formation in Pinto district, in which they have worked successfully for several years. The properties adjoining the Berryman M. Co. paid handsome dividends in 1872 and 1873, and have been very profitably worked since that time, on lease or by private capital. None of these mines have been prospected to any great depth, but recent developments, particularly in the Diagonal mine, show that the ore bodies continue as depth is attained. The intention of the Berryman Co. is to thoroughly prospect their ground, and, by vigorous work this spring and summer, determine its value. The surface ground is rich in fine float rock, and is broken up and mineralized at almost every point. Unless all mining signs fail in this instance, the company are likely to find something before next winter that will repay them for their expenditures, and develop a property that will add materially to the wealth of this mining neighborhood.

SACRAMENTO DISTRICT.

MINING CLAIM SOLD.—Winnemucca Silver State, March 30: It is reported that H. J. Bender, who has been prospecting for some time in Sacramento district, has disposed of one of his mining claims to Oakland men, who intend to develop it. The ledge is in Sacramento district and is called the Philadelphia.

TAYLOR DISTRICT.

REPORTED SALE.—Hamilton Pine News, March 31: News reaches us from Hamilton that the report was current there that the Monitor property, in Taylor district, had been sold to California parties for the handsome sum of \$300,000; and the Gore mine, owned by Joe Carothers and M. B. Garaghan, for \$50,000.

TUSCARORA DISTRICT.

NORTHERN BELLE.—True Figure, March 31: The west drift from the bottom of the main winze from the fifth shaft level, has been extended 14 ft during the week, its total length now being 48 ft and the face is in a much softer formation. It is still showing sulphurets giving low assay. The shipments of bullion were valued at \$13,617.98 for the week ending March 29th; and the total shipments to the same date on March account being \$52,950.03. Another shipment on this month's account is yet to be made.

MOUNT DIABLO.—The slope above the connecting drift between winzes No. 1 and 2 shows 15 inches of \$70 ore. The east slope from winze No. 2 has developed 18 inches of ore assaying the same amount. There is a body of ore 2 ft in width, and of a value of \$75 per ton, in the intermediate slope, below the third level and west of winze No. 1. The stopes from the raise, north of the shaft on the second level, are turning out some ore that assays \$70 per ton, and those above the west drift from the Callison winze, are yielding several carloads of \$70 ore daily, and are looking well. An 18-inch ledge of \$100 ore has been found in the hanging wall of one of these stopes, and has an encouraging appearance. A shipment of bullion amounting to \$5,552.09 was made on the 27th inst.

WHITE PINE DISTRICT.

HAMILTON'S PROSPECTS.—Cor. White Pine News, March 31: It is current report that the Eberhardt tunnel is looking well and they will shortly resume work with their Burleighs. Captain Drake wears a smiling countenance, looks wise and says little. The Sweetwater Company has secured the services of Mr. Sam. Liddle, who has been with the Eberhardt Company for 13 years. Under his efficient management the Smoky mill is being thoroughly overhauled and put in tip-top shape in every respect, new pans, etc.

Arizona.

CASTLE CREEK SMELTER.—Gazette, March 30: The smelter for the Castle Creek copper mines, controlled by the Collier Co., is expected to arrive at Maricopa, the latter part of next week. The company now has about thirty men at work on the road, leading from the mine to the site of the smelter, in Castle Creek, a distance of about two miles. At present there is quite a respectable settlement at the Collier mine and also at the Jones Springs, and after operations are once commenced it is presumed that a still larger number will be there. No work is at present being prosecuted in the mine, nor will a force be put on until a smelter is in readiness, inasmuch as there is plenty of ore out already for quite a respectable run.

NOTES.—Mohave Co. Miner, March 25: Robert D'Yhr informs us that he expects some parties out from Chicago very soon to examine the Oro Fino mine, owned by himself and Louis Davidson. The mine is looking splendidly. Work is being vigorously prosecuted on the Indian Boy mine, at Stockton, and arrangements have been made to ship large quantities of the ore to the Hubbs smelting works at Albuquerque. There are quite a number of new locations being made in the Cedar district, and several rich finds are reported. Cadden and Ewing have made another rich strike on the Diana mine, at Chloride. In crosscutting the ledge in a new place, they found a streak of ore two feet wide, showing horn silver, which he says will go \$400 to the ton. The ledge is twelve feet wide. Davis & Styles have gone to Music Mountain to work on the Fairview mine. H. A. Owen, familiarly known as "Chloride Jack," was in town last Wednesday, accompanied by John Gird. They left here on Thursday for Owens' copper claims in Cedar district. Ed. Cavanaugh is working on the Snow Flake mine, at Layne Springs, and is taking out some good ore.

NEW DISCOVERY.—Arizona Miner, March 31: About ten days since, Mr. James Tighe, a miner residing on Lynx Creek, discovered, near Knapp's

Gulch, a very wonderful ledge, rich in gold and silver. Croppings presented for our inspection carry gold in abundance, and is entirely free from sulphurets. Assays made show the ore to carry about \$150 in gold, and \$150 in silver. From the location of the ledge, only two miles from Howell's smelter, its width two feet, the character of the ore being high grade and free, we consider this one of the best finds for Lynx Creek yet made. Mr. Tighe has located, in this valuable property, with him a well known mining man of southern Arizona—Mr. Hugh Hutchinson—who will, no doubt, find his way here very soon, and open up this excellent property. Mr. Tighe, who, by the way, is a typo, has named the new discovery M. O. D. Extensions have been taken up, and the general impression is that the most valuable ledge of the district has just been found. Thus we have it, new men continually discovering in the vicinity of the capital of Arizona, bonanzas which have escaped the notice of "old timers." We are always pleased to hear of the good luck of new comers to our country. There are yet hundreds of fine properties undiscovered, awaiting the advent of the right one. Even though a hundred years shall lapse before that time arrives.

THE HOWELL SMELTER.—Arizona Miner, March 31: Few people, even amongst those who visit the Howell smelter, appreciate the magnitude of this institution. The placing of works of this size, costing, when completed, at least \$200,000, is certainly an earnest of the belief which Mr. Howell and his associates have in the permanency and richness of the mines in the vicinity of his smelter. So great has been the effect of the location of the smelter, that a town has sprung into existence near it, and houses have been erected all along the creek for a distance of over a mile above. Hundreds of men are at work in the vicinity of the smelter burning coal, and the hills and mountains are full of prospectors, and miners are taking out large quantities of ore from various localities. Dr. Mulvane, one of the A. & P. railroad company directors, visited the Howell smelter and inspected the mines in the vicinity. The gentleman was much pleased with the mineral wealth of Yavapai county, and his visit will no doubt have some effect in hastening the building of our railroad. The Howell smelter is the most extensive and marked enterprise ever inaugurated in this county, and marks an era in our prosperity which will soon be felt throughout entire Northern Arizona.

DOS CARREAS COPPER CO.—Tombstone Epitaph, April 3: Copper mining is being carried on quite extensively in camp. Many copper mines that were thought to be worthless have lately been located, and work commenced on them, and all show well as work progresses. Among the best are the Starr King, Isabella and Green Monster, all three on one ledge and owned by W. F. Bennett. The ledge runs north and south, and is at least 100 feet wide the entire length of the three claims. High-grade copper ore is found in different places. On the Starr King and Isabella ore is found that assays as high as \$80 in gold and \$30 in silver, and nearly all the ore assays from four to fifteen per cent. copper. Some few men are working on Emersy's mines, taking out ore for shipment. The Commonwealth company has stopped all work on their mines in Wood canyon, and Mr. Nash, the superintendent, has gone to San Francisco. The president of the company is expected here in about a month, when it is thought work will be started again.

Colorado.

LEADVILLE NOTES.—Herald, March 31: The Wilson tunnel, on Printer Boy hill, is making steady shipments from a good body of pay ore. The Nellie S. ore body continues to improve and now shows over twenty feet in thickness. Regular shipments are being made. The south end of the Fannie lode is being worked under a lease, by Postmaster Jones, of Oro, and shows some good looking ore. About fifteen men are now employed upon the Florence, on Printer Boy hill, and a new shaft is being sunk near the Nellie S. line. In the Birdie R., on Sugar Loaf, the levels have been started north and south at a depth of 100 feet, and both show two feet of ore. The Eagle M. Co. is working three shifts on the Bob Sheppard lode. They have a very fine plant of machinery, and are pushing development. Sam Ford and others are working the Paymaster, in Iowa gulch, with very favorable prospects. A body of iron and hard carbonates has already been opened up in the present workings.

GILPIN COUNTY.—Register-Coll, March 31: The National bank shipped, yesterday, \$5,900 in gold bullion. Hanington & Mellor shipped \$3,500, a total of \$9,400. Supt. Geo. W. Barrett, of the Rollins G. & S. M. Co., left at the First National bank, yesterday, two golden eggs, or retorts, having an aggregate weight of 130 ounces. The retorts were the result of a two weeks' clean up of 31 stamps employed in crushing ore from the Perigo mine, on Perigo mountain, Independent district. The excitement over the recent finds of silver bearing ore on the mountains east of North Creek, below the toll gate in Black Hawk is unabated. The last strike reported is that made day before yesterday by James Fisher, of Central. James is a practical miner and is not easily excited, but he insists that he has a good vein uncovered. As the snow disappears west of the city, prospectors begin work on locations made by them last summer.

Idaho.

WOOD RIVER ITEMS.—Wood River Times, March 30: The men driving the Strahorn tunnel, in Bald Mountain, opposite Hailey, cut through a ledge, yesterday, which carries ore, and the ground in the face is becoming softer with indications improving for a strike ahead. Dr. S. B. Miller is purchasing tools and supplies to place miners at work upon the Rising Sun mine, owned by his company, as well as upon the Great View mine. These two locations join Barney Quigg's claims. The Rising Sun is supposed to be the extension of the Ophir, and on the O K vein. William Gaughan has cut a ledge near the O K boarding house and located all the ground unlocated, which gives him a fraction only, but if the ledge opens well it will be a good property. The Lincoln group, after patents shall be secured, will be incorporated, and a company organized at Chicago, under the laws of Illinois, to develop it. Martin Curran has continued work upon his find of a month ago, and yesterday came into a larger body of galena. The claim is in the sidell back of the Bullion company's office. Mr. Curran

is now superintendent of the Wood River Mining Company.

SAWTOOTH.—Salt Lake City Tribune, March 30: One of the most promising mining districts in Idaho is that known as the Sawtooth, located north of Wood River, just beyond the divide, at the headwaters of the Salmon river. This district has been in the way of development the past three or four years, and yet no very decided progress was made until the seasons of 1881-2. Now the numerous properties have so far advanced that we may confidently look for a large output of ore and bullion this season. In Vienna Gulch the mines are looking remarkably well, and the 20-stamp silver mill is so far completed and supplied that in a few weeks it will begin sending bullion to market. In Sawtooth Gulch there is the Columbia & Beaver mill in readiness for work as soon as ore in sufficient quantities can be had to keep it going, and this can be had, we understand, as soon as the company is ready to purchase. There is a bright promise of active times in this gulch as soon as the season fairly opens. The Milgrim mine, at the upper end of Beaver Gulch, has been so well developed as to need a mill to reduce its ores. Further up, and near the summit of the Sawtooth Range, is located the property of the Sawtooth Gold and Silver Mining Company of Idaho. This company is composed largely of Utah citizens, and may be considered a local organization, owning six valuable mining claims and having its capital stock divided into 150,000 shares, the par value of which is \$10 each. By the early completion of the railway to Hailey, Idaho, Sawtooth district is brought in such close connection with the road as to make property there more desirable than it has been in the past, and we feel confident that even better facilities are soon to be afforded by the extension of the road up the river to a point much nearer.

Montana.

SILVER MINES.—Inter-Mountain, March 31: Despite the accident which interfered with the extraction of ore from the Magna Charta for two days, and also the mislay which befell one of the mill roasters, necessitating its being stopped for repairs, the operations of the Alice company for the past month have been entirely satisfactory, and the bullion output will somewhat exceed \$50,000. Yesterday the new mill worked 6½ tons of roasting ore and the old mill 25½ tons of free ore, or a total of 92 tons of ore. The chlorinations were 84, the amalgamation 86, and the product of the day was \$3,216.94. In the amount of ore treated this is the best run the mills of the Alice company ever made. Developments in the Alice are progressing as usual. On the 100 south level 20 tons of free ore are extracted daily, which amount could be largely increased if necessary. The Magna Charta is producing, daily, 60 tons of ore, and keeps the stamps of the big mill well supplied. The most important development of the past week is the striking of the pay chute on the 500 level at a point 90 feet west of the crosscut, where three feet of 40 ounce ore is exposed. The condition of the Moulton at the present time is of a character to inspire even greater confidence than ever in its continued productiveness. The new surface strike recently recorded on the south vein is being developed with splendid success, the bottom of the shaft, which is now about 30 feet deep, being all in ore of exceptionally fine quality, locket samples assaying from 75 to 100 ounces. In the stopes between the 200 and 100 levels the ore body retains its width and richness, and the miners are extracting about 30 tons of 40 ounce ore per day.

New Mexico.

LOCAL NEWS.—Southwest Sentinel, March 31: A new discovery has been made in the Burro mountains, west of Bullard's Peak, and near the Gila river. Four claims have been worked and show a carbonate ore with galena and copper. The Pocahontas has a shaft 29 feet deep, with ledge three and one half feet wide, another eight feet deep and ledge eight feet wide. Little Chief has a 30-foot tunnel showing carbonates. The Carbonate Queen, near by, is now being prospected and shows galena, copper and carbonate running 80 ounces silver and 45 per cent. lead. These locations are owned by Christian, Smith, Michaels and Humphrey. Late reports from the Black Hawk show the mine is looking better than it ever did. As soon as the machinery for hoisting arrives a large amount of ore will be ready, and the Bullard's Peak district bids fair to be one of the best in the southwest. On the Silver King, in this same district, work is progressing rapidly, and the outlook of the mine improves as the shaft goes down. The Atlantic, owned by Messrs. Cases & Twomey has had some work done upon it, and the outlook is encouraging to the owners. The Young Ireland and Young America have one shaft of 30 feet, one of 80 feet and one of seven feet. The ore in each looks well. These claims are owned by Messrs. Carey and Kerr. Reports from the Black Diamonds show the streak is looking better than formerly. A contract for sinking 25 feet has been let on the Morrison claim. This will make the present shaft some 40 feet deep. It is the intention of the owners to sink further. The vein is 18 inches wide close to a smooth foot-wall of granite.

Oregon.

NOTES.—Jacksonville Times, March 31: Placer miners have generally been disappointed by the unusually dry winter season. Wimer & Sons have their mine, near Waldo, in good running order, and expect to make a big clean up. H. L. Hanson has sold his interest in the drifting claims, near Applegate postoffice, to his partner, Thos. Berryman, for \$600. Bybee & Co. are still working their mines, near Waldo, with half a head of water. They will next raise the source of their ditch, when a good supply will be afforded them during the greater part of the year. Green Bros., of Galice creek, have a large amount of ore on their dump, which will pay from \$50 to \$100 to the ton, and are probably crushing it before this time. They have a rich ledge, that is constantly improving. The Roseburg Plunderer, speaking of the smelting works that W. Q. Brown & Co. propose putting up at Piney, Douglas county, says that they are intended to be of a sufficient capacity to give employment to 150 persons. W. W. Graham, who is engaged in mining in the Siskiyou mountains, was in town this week. He reports that several claims are being worked on Grouse and Beaver creeks, with promising results. His company are groundsluicing just below the mouth of Grouse creek, where coarse gold seems to exist in considerable quantities. Patterson Bros. have a hydraulic and giant, and are piping with good effect. The other miners also seem to be doing well.

An industry dependent upon charcoal as fuel must, to be permanent, maintain large forest areas, thus benefiting the surrounding country and much of the growing timber being suitable

for other purposes than charcoal-making, will be so used whenever the compensation is greater. Anomalous as it may at first appear, the probabilities are that, in the near future, the large consumers of charcoal will be among the most enthusiastic patrons of forest cultivation and preservation.

THE ENGINEER.

THE CHANNEL TUNNEL. The foolish discussions of the English politicians in regard to the military problems and dangers to England from the construction of the Channel tunnel do not seem to have much influence in retarding the actual work upon that great engineering work. The new plans issued by the channel tunnel companies contain some important alterations, both companies having altered or amended their original plans with a view to meet the requirements of the objections or recommendations of the channel tunnel commissioners. The amendments shown by the southeastern company are a great improvement in point of defensibility on their previous plan. It is proposed to carry the present lines inland to the extent of about three miles, and then run down the Alkham valley, forming a detour and joining the southeastern main line at the Pier station. This would bring the entrance and approach to the tunnel well within the range of the defenses of the garrison of Dover. A branch line will also connect the London, Chatham & Dover line at the upper end of the town. The channel tunnel company have abandoned their plan of beginning the tunnel at Dover, and have reverted to their old scheme of commencing a descent to the base of the tunnel at St. Margaret's, in the vicinity of Kearsney, about three miles from Dover. Another item reads as follows: The channel tunnel scheme is vigorously agitated, with a view to securing concessions in its favor. By the one mile and a quarter bore on the French side, the French engineers have shown they can proceed to Dover at the rate of 132 feet daily. This would complete a gallery the whole way across in a little over eighteen months. French enthusiasm on the subject takes no account of the English opposition.

FROM SEA TO SEA—ONCE MORE.—Mention has already been made, in this column, of a proposition to construct a ship canal from the head of navigation on the Tyne, which empties itself into the North Sea, to the Solway Frith, which enters the Irish Sea. The distance from sea to sea is about 80 miles, of which but 12 are navigable. The mouth of the latter is flat and for some distance up is a naked flat at low tide. The tides upon the opposite coasts are very large and return with great violence. The spring tides upon the North Sea coast have a rise of 18 feet; upon the coast of the Irish Sea the flow is 11 feet. Of course one or more locks will have to be constructed in connecting the waters of the two rivers. The work will be one of great interest to the coast commerce of Great Britain. Engineers are engaged in the necessary surveys for the preparation of plans and estimates. In the meantime a notice of motion in favor of the project has been given at a meeting of the Newcastle Town Council.

DRIVING PILES WITH DYNAMITE.—A correspondent of the *United States Miller*, in Budapest, Austria-Hungary, in a recent letter, mentions an interesting experiment in pile-driving by the use of dynamite. The piles experimented on had already been driven by an ordinary pile-driver, but it was desired to drive them down further. An officer of the military engineer corps was detailed to superintend the experiment. The piles were squared and the top covered by a wrought-iron plate fifteen inches square and four and a half inches thick. A seventeen and a half ounce charge of dynamite in the form of a cake six inches in diameter, wrapped in paper and clay was placed on the centre of each plate and fired. The effect produced was estimated to be equal to five blows of a 1,500-pound hammer, falling from a height of ten feet.

FROM THE BALTIC TO THE OCEAN.—Again the new ship canal between the Baltic sea and the German ocean is coming to the front. It will save a journey of 600 miles for a vessel making a trip between either of these waters, as the circumnavigation of the Peninsula of Jutland will be unnecessary. But the possession of this canal will necessitate Germany becoming a first-class naval power, with all the expense and responsibilities which that involves. In all, the proposed canal will be only fifty miles, or half the length of the Suez canal, and it will extend from Glückstadt to Kiel.

A GREAT NEED.—There can be no doubt, says the *Engineer*, that the inventor who could supply in a really portable form a machine or apparatus which would give out two or three horse power for a day would reap an enormous fortune. Up to the present time, however, nothing of the kind has been placed in the market. Gas is laid out to most houses now, and gas engines are plenty enough, yet they do not meet the want which a storage battery may be made yet, perhaps, to supply.

FLOODING THE SAHARA.—Recent telegraph dispatches from Tozer, Tunis, say that De Lesseps has arrived there. He asserted that explorations make it plain that creating an inland sea in the desert of Sahara is practicable, and it can be accomplished by using 100 excavating machines, equal in the aggregate and capacity to the labor of 100,000 men.

USEFUL INFORMATION.

Improvement in Shoemaking.

The *Boston Herald* gives the following account of a new process in sewing shoes, the invention of Mr. Lee E. Moore of that city, which it is said promises to revolutionize the whole business, being extremely simple but decidedly practicable, as it is equally applicable to ladies' work as to that of heavy work for men. Heretofore in the manufacture of hand-sewed work, the upper leather, which remains after sewing the welt to the inner sole, has either been cut off or tacked down and the space filled; but by the new method the upper, after having been fastened to the sole, is turned back over the welt, and in turn is again sewed to the outer sole, thus making the boot doubly strong, and making it virtually waterproof. In case a poor inner sole is used, so that the sewing gives way, the welt still acts as a lever, and there is no possibility of the upper pulling out. In the manufacture of common work for women, where machines are used, there is a rough seam left on the inside of the shoe, which is decidedly uncomfortable to the wearer, whereas if made by the process alluded to, the inside of the boot is left perfectly smooth. Then, again, by the old method nails are used to a greater or less extent in lasting, which in due time give the wearer unmeasurable discomfort, but this is entirely obviated by the new process, as no nails are used as the upper does not require to be fastened to the inner sole except by the sewing. Those who have investigated the process are loud in their praises, and compliment the inventor highly upon his success, and it is a fact that manufacturers of shoe machinery are already at work endeavoring to produce a machine which will accomplish the work which is now done by hand, and with a good prospect of success. This process, it is stated, enables hand-sewed goods to be made within a few cents per pair of cheap machine work.

DYEING LEATHER.—In the glove trade the leather has hitherto always been dyed by brushing on the dyes by hand. The defects of this method are: Its slowness, the occurrence of large, soiled edges on the fleshy side, and notwithstanding every care being taken, the uneven character of the dye produced. To avoid these, Joseph Kristen, of Brunn, has a process in which even dyeing is obtained by the application of centrifugal force. The skin to be dyed is fixed on the center of a horizontally rotating disc; the color is also fed on to the center, and by the rapid revolution of the disc is spread equally over the whole surface. The color is forced on to the disc by means of a pump, or it merely flows from a reservoir standing at a higher level. The excess of color driven off at the edges of the revolving disc is collected and used over again, until the skin is fully dyed. To dye one skin by this method takes from ten to fifteen minutes. A single pump may serve at least for five machines, which would require only one attendant, so that, by the above arrangement, one man could, in twelve hours, easily dye 150 skins, possessing great evenness of dye and free from spotting.

AN "OLD CURIOSITY SHOP" will be one of the features of the approaching Railroad Exhibition at Chicago. The building will be especially designed for its purpose, and will contain a most interesting collection of the earliest railway appliances, and curious and attractive articles from every department of railway service. One of the most remarkable objects in this collection will be George Stevenson's "Rocket," the first locomotive ever built. A cablegram from Commissioner Peters, who resides in London, states the directors of the South Kensington Museum have consented to permit their almost sacred relic to be sent across the Atlantic to be placed in the exposition. Several other very old locomotives have already been secured for the exhibit, one of which will be brought here by the engineer who ran it forty years. The universal attention which this exhibit and others to be located in the annex will attract must necessarily make the ground space of the court as valuable and desirable as that in the present building.

CHEAP BLACK INK.—The *Industrie Blatter* recommends the following formula as furnishing a good and cheap writing ink: French extract of Campeachy wood, 100 parts; lime water, 800 parts; phenol (carbolic acid), 3 parts; hydrochloric acid, 25 parts; gum arabic, 30 parts; red chromate of potash, 3 parts. The extract is first dissolved in the lime water on a steam bath, with frequent stirring or shaking, after which the carbolic and hydrochloric acids are added, and change the red color to a brownish yellow. It is then heated half an hour on steam bath and set aside to cool. It is next filtered, and the gum and bichromate, dissolved in water, are added. Enough water is then added to make up the solution to 1,800 parts. This ink is a fine red when used, but soon gets black.

UTILIZING COTTON SEED.—One ton of cotton seed yields thirty-six gallons of crude oil, worth about \$18. The hull from a ton of seed weighs 900 pounds, and the meal before pressing weighs 1,100 pounds. The oil cake is worth \$27 to \$30 per ton. It is calculated that there is a net profit of about \$9 in grinding the seed of a bale of cotton.

MARQUETRIE WORK. Of recent years inlaid veneer or marquetric has attained a remarkable position, and may be said now to have established itself as a permanency in the cabinet work of the age. A quick way of making this inlaid work that has been employed in the United States for some time, is to arrange the pieces of veneer alternately walnut and maple, for instance—and with a very fine marquetric saw cut the pattern through all the pieces as they lie piled upon each other, thus arranged according to the kind of wood. When this is done the cabinet-maker has a quantity of veneers before him of various woods with the pattern cut out of each, and on the other hand a quantity of fragile cuttings in the larger pieces. All that is now necessary to be done is to set the maple pattern in the walnut veneer, or vice versa, and the marquetric is complete. This has the double advantage of cheapness and durability, and the process is one that has the merit of allowing rapid work, and usually of a satisfactory character.

JOINING LEATHER TO IRON.—The best cement for joining leather to iron, as for covering iron pulleys, is said to be made as follows: Soak equal parts of common glue and isinglass for ten hours in just water enough to cover them. Bring the whole to nearly the boiling point, and add pure tannin until the mixture becomes ropy, or appears like the white of eggs. Buff off the surfaces to be joined, apply the cement, and clamp firmly.

COPPER IN BREAD.—Some time ago Dr. J. Vander Bergh was struck with the constancy of the proportion of copper found in bread, and made an examination of wheat. In 1,000,000 parts of the grain were 9.24 of metallic copper, and oats yielded 10.8 parts in the same quantity. He made, of course, the usual preliminary tests to ascertain the purity of his reagents, and he took care that his gas burners were made of iron. Even the porcelain capsule was supported on a platinum triangle.

BLACKING IRON AND STEEL.—A brilliant black can be produced, it is said, on iron and steel, by applying, with a fine brush, a mixture of turpentine and sulphur boiled together. When the turpentine evaporates there remains on the metal a thin layer of sulphur which unites closely with the iron when heated for a time over a spirit or gas flame. This varnish protects the metal, and is quite durable.

A CORRESPONDENT of the *American Machinist* gives this rule for finding the length of a belt to connect two shafts having unequal pulleys: Add the diameter of the two pulleys together, divide the result by two, and multiply by three and one fourth; add the product to twice the distance between the centers of the shafts, and you have the length required.

GOOD HEALTH.

Sleeplessness.

Druggists tell us that there is a growing demand for various medicines and preparations containing opiates in one shape or another. People wreck their nervous systems by injudicious habits of life, and the result is unsound sleep, dyspepsia and countless other evils. A little advice to such persons may not be out of place. They should, of course, be careful to abandon that method of life which brings them into physical disorder. Their complaint may be fed by tobacco; narcotics should be avoided. One cause of their trouble may be that they take insufficient outdoor exercise. Perhaps they drink too much tea or coffee, or eat too much flesh meat. There are a thousand practices allowed by convention which are themselves harmful and prejudicial to the health.

The quality of sleep may be improved by diminishing the length of time spent in bed. A hot shower bath at bed time cleanses the skin and predisposes sleep. Many a toiling business or literary man goes to bed tired and worn out, only to toss about wearily from one side to another. His brain is hot and full of blood, while his feet are cold. He thinks over again the thoughts that have been engaging his attention during the day, or does over again the business that has called forth his energies for twelve or sixteen hours past. His night is a round of tossing to and fro. Is there any wonder that, failing to find out what is the true and natural remedy for his pains, he resorts to opiates, which he knows will give him temporary relief.

The want of balance between mental and physical labor is a fruitful cause of sleeplessness. Many a business man, whose duties keep him in an office all day, would improve his health a great deal if he were to fit up his attic as a carpenter's shop, and spend an hour therein after supper. This, of course, would be beneficial only if he happened to have a liking for mechanics; then he would find his occupation afforded him amusement, mental occupation, and muscular effort in just the proper proportions.

Some people waste their nervous energy through morbid introspection and dwelling upon the past. Some can do with ease as much physical labor as would kill other men. The same is true of mental labor. Strict honesty, regular habits, a careful diet, plenty of exercise, and a clear conscience—with these a man need not suffer much from sleeplessness.

Surgery for Engineers.

It is beginning to be understood, says the *Scientific American*, that a limited knowledge of operative surgery, certainly enough of the art to enable a man to tie an artery, staunch a flow of blood, or bind up the wounds of an injured workman or traveler, is highly desirable, if not vitally necessary, to mechanics and engineers. This is especially true of the foreman of machine shops, engine drivers and civil and mining engineers. In many manufacturing operations, and in all works of constructive and mining engineering, accidents are always liable to happen, and not infrequently the needed surgeon is miles away. In any case, the advantage of having close at hand some one familiar with the first treatment of serious hurts, who can do what is needful to be done in such emergencies to keep the patient's life from wasting before the regular surgeon's help can be obtained, is beyond question. Hitherto, so far as we know, provision for this important line of instruction for young engineers and foremen in constructive works has never been made by our technical institutions. The trustees of the University of Pennsylvania, however, have now taken the first step in a movement in this direction, and have engaged a lecturer on operative surgery to give a course of lectures on surgery to the senior scientific classes of the collegiate department of the University, especially the mining and engineering sections. The innovation is a good one.

LIME JUICE IN THE TREATMENT OF DIPHTHERIA.—M. Czartorski, M. D., of Stockholm, California, writes as follows to the *London Lancet*:—During a prolonged residence in the interior of China, I became acquainted with the fact that the Chinese place great reliance during epidemics of diphtheria on the internal use of the fresh juice of limes, and of the fruit itself, which they consume in enormous quantities, in every conceivable form—as lemonade, with native spirits, cut in slices, etc.—during attacks of this dreadful disease, with apparently most successful results, it hardly ever failing to effect a cure. The Chinese consider it a specific, and will, in case of need, do anything to obtain a supply. Since I have come back to California, as also in Louisiana, I have used limes and their juices in my practice as a physician with most successful results in cases of diphtheria, even in the most desperate cases. As soon as I take charge of a case of diphtheria, I order limes to be administered as freely as possible, in any manner the patient can be prevailed upon to take them, especially in the form of hot lemonade, sweetened with white sugar or honey, or cut in slices with powdered white sugar. Besides lime juice (which I suppose acts by imparting an excess of oxygen to the circulation, and thereby prevents formation of vibrios, etc., and so has almost a specific effect on disease.) I prescribe whatever drug may be indicated to relieve symptoms as they develop, and impart strength by appropriate stimulants and nourishment.

SIMPLE ANTIDOTE TO NICOTINE.—M. Armand (*Chemical News*) states that the deleterious effects of the use of tobacco can be counteracted, if not entirely annihilated, by moistening the tobacco when in course of preparation, previous to its delivery to the consumer, with a strong infusion of watercresses, since the author has discovered that this vegetable contains principles which, without destroying the peculiar aroma of tobacco, destroys the deleterious effects of nicotine.

LONG CONTINUED BATHS.—Professor Kaposi of Vienna has introduced continuous baths for skin affections. The patient is placed in them on a mechanical bed, and remains there for fifty or one hundred days, not only taking his meals, but sleeping while thus immersed in water. The *Progres Medical* pronounces them successful, and recommends their introduction into the Paris hospitals.

LIME WATER AND MILK.—Experience proves that this mixture is food and medicine both to the young and old, when the functions of digestion and assimilation are feeble. A stomachaxed by gluttony, irritated by improper food, inflamed by alcohol, enfeebled by disease, or otherwise unfitted for its duties, will resume its work, it is said, and do it energetically on a diet of bread and milk and lime water; four table-spoonfuls of the latter to a pint of milk.

THE problem of life has been solved by an Italian who keeps an eating house in New York. His bill of fare is governed by the following regulations: Coffee or tea, per cup, one cent; soup, per bowl, one cent; pie, per cut, two cents; beefsteak, four cents; roast meats, four cents; chicken stew, five cents; ham and eggs, eight cents, etc. Many a hungry stomach desires to know "Where's his place?"—*N. Y. Graphic*.

TO DESTROY WARTS.—A correspondent of the *British Medical Journal* (Jan. 13th, p. 90), states that he has found the application of a strong solution of chromic acid, three or four times, by means of a camel's hair pencil, to be the most efficient and easy method of removing warts. They become black, and soon fall off.

Passing Events.

The fine weather which has prevailed since the recent welcome rain storm in this State has been good for both miners and farmers. The streams all increased in volume, and made water plenty, and the reserves of snow in the mountains ensure water for some time to come. The coming season will be much more prosperous than was hoped for.

This month many hundred prospectors start out on their season's work. In the more temperate regions they are now on the hillsides, and they are following up the melting of the snows in the colder and more mountainous lo-
cations.

It is worthy of note that the strike reported in the Contention mine, at Tombstone, Arizona, of a fine body of ore on the 600 level demon-
strates, almost to a certainty, the existence of mineral below the water level, and assures a bright future for the camp. The *Epitaph* states that the demonstration of this fact has been awaited with much suspense for months past, as it was felt that unless deep mining could be successfully prosecuted, it was hardly worth the expenditure of the time and money required to develop prospects only to water level. The striking of good ore almost at the water level is fairly conclusive to experienced miners that it will exist below, and a more secure feeling of the permanence of the mines and the attendant business prosperity of Tombstone is felt.

Determining Sediment in Suspension in a Stream.

A knowledge of the amount of sediment being carried at any given time in a stream is something people often want, especially in California. But the fact is that the determination of the quantity of sediment carried in suspension by a stream requires much skill and care, and any observations taken by an unskilled observer will show exaggerated results. For the use of miners and others we here give the proper method of determining the amount of solid matter carried in suspension by a sediment-bearing stream:

First—The samples taken must fairly represent an average or mean of the whole water flowing; therefore samples should be taken as nearly at the same time as is practicable from different points, both in depth and position in the stream.

Great care in obtaining these samples must be observed, or exaggerated results will be arrived at. If the vessel in which the water is caught is allowed to remain for any length of time in the stream, sediment will necessarily be deposited in it, coming from other water than that held by the particular water contained in the vessel, as the current of the stream will be somewhat checked by the vessel itself, which, of course, results in the deposit or dropping of sediment.

Hence, engineers in making such determinations take great care, and use apparatus especially prepared for this purpose. It must be kept in mind that any errors of this kind will throw always exaggerated quantities of sediment, and never too little.

Second—After samples are taken they are allowed to settle for quite a length of time; then the water is slowly evaporated by placing the vessel on hot sand. After the moisture has all evaporated the residuum of sediment is weighed, and this result compared with the weight of the sample as first obtained. The proportion between the weight of the sediment and the weight of the sample shows percentage by weight.

The problem, however, is to determine the percentage or ratio by volume. To obtain this the ratio by weight must be divided by the specific gravity of the sediment. This is generally accepted by engineers as 1.8 or 1.9. Therefore the percentage by volume is about one half of the percentage by weight.

After knowing the mean or average amount of sediment in the stream, and also knowing the total amount of water flowing past in the stream in one second, or any fixed period of time, it is an easy arithmetical problem to determine the gross amount of sediment carried in suspension. In a large stream, such as the Mississippi, there is a considerable quantity of sand rolled along the bottom by the current. This, Generals Humphreys and Abbot, in their elaborate surveys of the Mississippi, occupying nearly ten years' time, determined roughly to be one tenth of the amount held in suspension.

The following examples will show a calculation:

A stream with 1,000 cubic feet of water per second flowing into it.

A mean sample shows that in 1,000 grains of water there are 8 grains of sediment.

8-1000 equal .008, or 8-10 of 1%.

Dividing this by 1.8-10 (specific gravity), we have 44-100% by volume.

Now, 1,000 x .0044 = 4.4 cubic feet of sediment carried past each second in suspension.

THE SUBMARINE TUNNEL BETWEEN ITALY AND SICILY.—From the project presented to the Italian Ministry, and proposed to the Venetian Society of Construction, by Signor Gabelli, the following particulars are taken: The length of the submarine tunnel between Italy and Sicily will be 44,000 feet. The maximum depth of the sea above the line of tunnel is 363 feet. The thickness of rock between the roof of the tunnel and the bottom of the sea is 115 feet. The direction of the tunnel from St. Agata to Punta del Pizzo is almost due northwest to southwest. The two inclines descending to the tunnel will first run parallel with the shore, and then descend to the lowest level by spiral tunnels. The length of these inclines is each 15,000 feet, and the area occupied by each spiral tunnel is 1,160 feet. The degree of inclination will be 35 per 1,000. The center of the tunnel will be on a higher level than the two ends. Wells and subsidiary tunnels will be constructed to drain off the percolating water, and the most difficult part of the line will be first commenced, which will at once show the geological construction of the ground and the difficulties to be overcome. According to the opinion of all geologists, the bottom of the Straits of Messina consists of crystalline rock (granite, gneiss and mica schists.)

New Species of Genus Homo.

At the meeting of the California Academy of Sciences, held on Monday evening last, Dr. H. W. Harkness presented some interesting facts of value to the world of science. He presented to the museum the lower jaw of an animal found in the sandstone of the Nevada State prison quarry at Carson. This specimen, which was in a fine state of preservation, was pronounced by Mr. C. D. Gibbs to be a species of *machairodus*, or saber-toothed tiger. The doctor called attention to the fact that Mr. Gibbs, in his report upon the Carson footprints, had referred to one series of the tracks as having evidently been made by the above mentioned animal. This is a magnificent and valuable specimen from a scientific point of view, and Dr. Harkness was fortunate in securing it for a California institution.

It was feared by scientists of the Pacific coast that upon the retirement of Mr. Garrard from the control of the Nevada State prison, all interest of the authorities in this storehouse of fossils would cease. He was happy to be able to state that such fears are unfounded, as the present warden, Mr. Frank Bell, shows the liveliest interest in all the scientific questions involved, and is eager to assist the Academy in their investigations of this most interesting discovery.

By far the most important subject brought to the attention of the Academy by Dr. Harkness was, however, his description of a new species of the genus *homo*. It will be recollected that some months since Dr. Harkness described to the Academy the fossil footprints of the Carson quarry, and submitted drawings and casts of the footprints of what was apparently a man.

The subject has attracted great attention in the scientific world at home and abroad. As to the human footprints, there was some difference of opinion among scientists. Dr. Harkness has, however, made still more careful examinations of the tracks since that time, and his later observations fully confirm his previous opinion that the tracks are those of a hitherto undescribed species of the genus *homo*. At the meeting the other night he submitted the following description of the new species:

"*HOMO NEVADENSIS*, Harkness.—Length of track, 18 1/2 inches; width at the ball of the foot, 8 inches; width of heel, 6 inches; average length of step, 27 inches; length of stride, 54 inches; width of trackway, 18 inches, as measured from the center of the sandal to the center of the corresponding one. Angle with the median line, about 15°. Each track is being modified in form by a sandal, or other protection to the foot."

Dr. Harkness also gave a name to a new species of wolf, the tracks of which are seen at the same quarry. The provisional name is *Canis Carsonicus*.

There is no doubt that this discovery will lead to still further discussion in the scientific world. A new species of the genus *homo* is not a "find" like a new plant or ordinary natural history specimen. The "Nevada Man" will attract attention all over the world. Excavations in the quarry still continue. In view of the fact that they have found the teeth of the saber-toothed tiger, the horse, and mastodon's tusk and jaw, and a horse's jaw, it is not improbable that still more interesting finds will yet be made.

OREGON AND WASHINGTON.—We are pleased to announce that our esteemed agent and correspondent, Mr. A. C. Knox, will visit Oregon and Washington Territory in the interest of our journal. Mr. Knox has had long experience in this branch of our work, and we can recommend him to all our northern friends with much confidence. We desire to give fuller information concerning the industrial progress of the northern regions of our Pacific Coast empire, and by the use of good illustrations and descriptions contribute to the commendable work of making those desirable parts of our national domain much better known. There should be a perfect reciprocity of interest and co-operation between the different States and Territories of this coast. Each can learn something from the other, and thus contribute to the general development of the country.

MINING SURVEYS.—The Commissioner of the General Land Office has ruled that the fact that a mining survey upon which is an application for patent, conflicts with a prior survey does not prevent the applicant from including the conflicting area in his application, provided no application for patent upon such previous survey has already been made. Priority of application, and not priority of survey, governs in such matters. Of course a survey must show all conflicts with any previous surveys; but the mere showing of conflict does not divest the applicant of any legal rights.

Death of Peter Cooper.

The well known philanthropist, Peter Cooper, died of pneumonia, at New York, on Wednesday last, at the ripe age of ninety-three. Perhaps Mr. Cooper was better known as the founder of the "Cooper Institute," in New York, than for anything else, although his life has been a very useful and exemplary one in many respects. He was a skilled inventor, and emphatically a self-made man. He was apprenticed to a coachmaker when seventeen, and at the end of his apprenticeship began work on an improvement in the machines for shearing cloth. When this invention took tangible shape, Cooper found that he had made his first step toward fortune, as these machines were in great demand while the importation of foreign cloth was prohibited, during our war with Great Britain, in 1812-15. Afterward he went into the manufacture of cabinetware, then into the grocery business, and finally began the manufacture of glue and isinglass, in which he amassed a handsome fortune. He was, however, at different times, engaged in other branches of business. In 1830, he built works for the manufacture of iron, and afterward a rolling and wire mill in New York, where he first successfully used hard coal in puddling iron. In 1845, he started a rolling mill in Trenton, New Jersey, where he was the first to sell beams for building purposes. He was one of the earnest promoters of telegraphic enterprises in this country, and for nearly a score of years he was President of the New York, New Foundland and London Telegraph Company. He was also among the first to become interested in that great scheme of internal navigation, the Erie canal.

Before the canal was ready for use the question of a propelling power for the boats that were to be used upon its waters began to be debated, and Cooper made an experiment of propulsion by means of an endless chain. Although abandoned at the time, his plan, under the name of the Belgian towing system, is now used on some sections of the Erie canal. Peter Cooper keenly felt the disadvantages under which he had labored when a youth in obtaining an education, and a plan for the instruction and elevation of young people of both sexes, rich and poor alike, took tangible shape in the now famous Cooper Union, the cornerstone of which was laid in 1854. In this institution which is "to be devoted forever to the union of art and science, in their application to the useful purposes of life," is afforded the amplest opportunity for education without cost. The institution now affords instruction to an average of 2,000 pupils annually. It has a school of art for women, with instruction in all branches of drawing, painting, wood engraving and photography. It also has a school of telegraphy for young women. In the evening free instruction is given in mathematics, practical engineering and practical chemistry, and free lectures are delivered in natural philosophy and the elements of chemistry. A large free reading-room and a library is open day and evening.

This library has been greatly extended in the past few years, and is a favorite resort of certain of the working classes of the great city. It has done a great deal of good. The Institute is maintained at a cost of some \$12,000 a month. Mr. Cooper has given it about a million of dollars. An inventor and manufacturer, who was at the same time a philanthropist and a millionaire, could do vast good with his money, and Mr. Cooper did it. His memory will always be kept green by the thousands he has benefited.

Peter Cooper was nominated by the National Greenback party for President in 1876, and received 81,740 votes. He leaves two children—Edward Cooper, formerly Mayor of New York, and Mrs. Hewitt, wife of Congressman Abram S. Hewitt.

BETTER CARS FOR IMMIGRANTS.—The California Immigration Association is inaugurating a new plan throughout the States of the west where the severe winters have a tendency to induce farmers of some means to seek homes in warmer climes. Their efforts are being seconded by the railroad companies, who have made concessions in fares, and as an inducement for the organization of companies to start from a given center, such as Council Bluffs and Denver, the Association has made arrangements to have the improved immigration cars furnished with carpets and curtains, making them very comfortable for the overland trip. The first installment will arrive shortly.

THERE WERE 1,342 immigrants arrived by the two overland routes during the past week. Only 269 of these were in transit, their destination being British Columbia. A settlement of about fifty French families who had been induced to immigrate to Canada, and who are disappointed, have, upon applying for information to the manager of Castle Garden, been referred to the Immigration Association of this State, and are expected to come here this spring.

THE President has asked the Civil Service Commissioners to visit New York to inspect the Postoffice and Custom House there before submitting their new rules to him. The women clerks are quite enthusiastic, as they are advised that, under a proper construction of the Civil Service act, there will be no distinction in sex in recommendations for admission or promotion.

Fresh Water Pearl Mussels.

[Written for the Press by ROBERT E. C. STARNES.]

Almost everybody who has lived in the country in the neighborhood of lakes, ponds, brooks and rivers, has seen fresh water mussels, for they are a common form of bivalve shell fish in such places. There are two principal groups of these—one with usually solid shells, with interlocking projections in each valve, which are termed hinge teeth; the other with rather thin shells, which are destitute of hinge teeth. The first, with hinge teeth, are called *Unios*; the last, *Anodons*. The word *Unio* means "a pearl"; the word *Anodon* means "without teeth." These are the principal groups which constitute the family *Unionidae*. The inside of the valves, as the two pieces which form the shell are called, is lined with pearl. Sometimes this lining is pink, again white, yellowish, or orange, and more or less translucent.

It is quite frequently the case, that the soft mantle of the animal contains the round or oval pearls used for jewelry, and fine or seed pearls are quite common in such shells as live in streams where the water is silty, or carries sediment part of the year. A grain of sand gets lodged in the soft mantle of the mollusk, and causes irritation, the same as a speck of hard matter is painful in the human eye; this causes the mussel to cover the grit with a coating of mucus, which hardens upon the outside of the speck, and gives it a smooth, pearly surface. All pearls are produced in this way, and many bivalve mollusks, both fresh water and marine, contain these concretions. At one time, the gathering of fresh water mussels for the pearls contained in them was an extensive occupation in Britain; the streams were systematically searched, and the business profitable; for a long time, however, it has ceased to be remunerative.

Some historians state that one inducement to the invasion of Britain by Julius Cesar was the alleged great value of the pearl fisheries; so, also, with the invasion and conquest of Florida by De Soto. The narratives of the old Spanish explorers and adventurers contain exaggerated accounts of the size and abundance of pearls in the hands of the American aborigines, and even recent historians have given more or less credit to the glowing accounts and ridiculous fables of the old Spanish soldiers and chroniclers. Undoubtedly many and oftentimes valuable pearls are found in the fresh water mussels which abound in the tributary streams of the Mississippi and other southern and northern water courses which drain into the Mississippi basin, but "bushels of pearls" as has been related as seen in the possession of the Indians by the Spanish soldiers of De Soto's time is simply an absurdity. What they really did see was probably the smooth, shining shells of a species of *Marginella*, which are pearl-shaped and of the size of large pearls. These are quite common, and have been found in quantities in many cases in old burial mounds in the Mississippi valley and around the Gulf of Mexico, where these shells live. Some idea of the number of species of the river and pond mussels may be formed by the figures of Dr. Isaac Lea, of Philadelphia, who has made these forms an especial study for a great many years. In Dr. Lea's "Synopsis of the Family of Unionidae," 1870, he says: "In the following tables there will be found in the family 1,069 recent species as admitted, 224 unknown to me or doubtful, and 183 fossil; in all, 1,476; and the synonymy, according to my views, is enormous, being 891." Of this large number, nearly 700 of the family are credited to North America, inclusive of Mexico.

Regarding the fresh water mussels, the late Philip Carpenter wrote: "As far as shells are concerned, this family forms the special glory of North America, and especially of the drainage area of the Mississippi. The American *Unios* are the most numerous, the most remarkable, and the most beautiful that are found in any portion of the globe. There is a special reason for this provision. In no other known portion of the earth is there so large an area covered with soluble limestone. The waters of the rivers being saturated with this would be unfit for many of its uses, were it not for the immense development of this group of heavy shells. The North American *Unios* may be regarded as so many water filters absorbing the lime from the water, and preserving it from re-absorption by their strong, horny skins. The muskrats also play an important part in this economy, being nature's great *Unio* fishers. They bring them up out of the streams, and leave the shells in heaps on the banks."

In the foregoing we get some idea of the position and importance of the fresh water mussels, as related to the molluscan fauna of North America, a glimpse at the part they play, the kind of work they perform in the grand economy of nature, and a momentary glance at the complementary and compensative methods and implements through and by means of which the processes of nature are performed.

There are four or five so-called species in California, Oregon, etc., and one ever so far north, at the Yukon river, in Alaska, where they are eaten by the natives; the California aborigines also used them for food, and in the Klamath river country large heaps of the empty shells may be seen on the banks, the Kitchen-middens, or refuse of ancient feasts and festi-

vals; so in other parts of the State. Similar heaps are found in the southern and western States; the remains of fresh water clam bakes which have almost outlasted the race and the tribes who participated on such occasions. The shells of some of the species are used in the arts, and buttons and various trinkets are made from them, but the true mother-of-pearl shell has the long and poetical name of *Margaritifera margaritifera*, from *Margaret*, a pearl, and *fero*, to bear; namely, the pearl bearer. This is a marine shell, found only in salt water, and in the seas of warm climates, like the Gulf of California, the Bay of Panama, among the South Sea Islands, and Southern India, Australia, also the Persian Gulf, etc.

While the shells of the fresh water mussels are quite distinct, the anatomy or soft parts—that is to say the animal—is very much like that of the salt water mussels which are so abundant on nearly every sea coast, where the shells may be seen attached to rocks; seaweeds, also, to the woodwork of wharves, particularly to the piles of such structures, and upon old wrecks. These sometimes contain small pearls, but they are dark colored and of no value. Like their fresh water relatives, these also are used for human food, and are eaten by both whites and Indians.

Rapid Tunnel Work.

It will be remembered that we gave, some little time since, a description of the Big Bend tunnel, Butte county, in this State, which is designed to take large body of water, in order that the miners may get at some rich ground in the "Big Bend" of the Feather river. The tunnel is sixteen feet wide and twelve feet high. Operations are being rapidly pushed at the tunnel, and the work done there lately has been very remarkable in point of speed. They are

ANODONTA CYGNEA, OR SWAN MUSSEL.

using a No. 4 compressor Burleigh, and four tunnel drills, or Burleigh carriage.

The following is the report of work on the Big Bend tunnel for the month of February, 1883.

Total number of holes drilled.....	939
Total depth of holes drilled.....	5,097 ft
Average depth of holes.....	5.6 ft
Time used in drilling.....	124 hrs. 30 min
Average time of drilling, per shaft.....	1 hr. 32 min
Number of working shafts for month.....	31
Drills sharpened.....	672
Carloads of rock removed.....	3,306
No. 1 Giant Powder used.....	2,650 lbs
No. 2 Giant Powder used.....	50 lbs

Total tunnel built to Jan. 1.....	390 ft
Total tunnel built in Jan. 1883.....	355 ft
Total tunnel built in Feb. 1883.....	293 ft

Total tunnel completed to Mar. 1, 1883, 1,047 ft.

Up to March 22d they cut 232 feet more, making a total of 1,279 feet built to March 22d. The last week in March they cut 118 feet, or a total of 350 feet in the month.

March order for the Big Bend tunnel machinery was given to Parke & Lacy of this city. They guaranteed the company that with the machinery offered the rate of progress in this large tunnel would be 250 feet a month from one heading. How much better has been done can be seen. We do not know that any tunnel on this coast in the same kind of hard rock has been driven at any such rate of speed. Messrs. Parke & Lacy were confident, however, that their machinery would do the work. They are able now to furnish either the Burleigh Air Compressors and Rock Drills or the Ingersoll Compressors and Rock Drills. The improved diamond prospecting drills now being introduced are sold without any restriction.

FRANK A. HILL, the well known inventor and patentee of agricultural implements in this State, having retired from the management of the Agricultural Works, at Benicia, is about to organize a company to build and work a new system of steam plowing, which, he believes, will revolutionize this class of work.

Early History of The Comstock.

[Written for the Press by ALMARIN B. PAUL.]

I note in your issue of Feb. 24th, and also in that of March 17th, observations on the early history of the Comstock, which, unintentionally, are not strictly correct. Mr. Chas. Schuchard says:

"It was in the spring of 1858 when Comstock presented to Maj. K. Allen, then Quartermaster General, in his office in San Francisco, a piece of black ore from Washoe. Mr. Allen showed the ore—the same—to Mr. Killalee." This is certainly a mistake, as far as Comstock is concerned, in two respects. First, Comstock knew nothing of the black ore until Stone, sent over by Harrison to Nevada, California, some of the "black stuff" for Comstock to see what it was, and had reported to him. This was in June, 1859; second, Comstock did not visit San Francisco until after he sold his interest, in December (I think it was), 1859. Again, Mr. S. says: "Killalee took the specimens to his office, and there made the assays. Shortly after, I learned Mr. Killalee was dead." Richard G. Killalee I was personally acquainted with; he died July 29th, 1859. Mr. S. is out of his reckoning, I think he will admit, just about one year. I will prove this fact further, as he says, "If I recollect right (which he don't), you may find some notes on this in Mr. Blake's *Mining Magazine*, published at that time."

Now for Prof. Blake and his *Mining Magazine*. In the article of Prof. Blake's in the *MINING AND SCIENTIFIC PRESS* of March 17th, 1883, he says:

Mr. Charles Schuchard, in his interesting communication (page 126), refers to some notes on the discovery of the silver ore of the Comstock lode, which he thinks were published in the *Mining Magazine*. He is correct in this reference. One of the first notices of the discovery (if not the first), outside of the notices in the daily newspapers of that time, appeared in the *Mining Magazine* for January, 1860, (second series, vol. 1, page 221). A short notice appeared also in the number for De-

So much for that subject, now I claim to be the first individual who gave notice through the public prints of the discovery. It was published in the *San Francisco Bulletin*, July 2 or 3, 1859, and was as follows:

Rich Gold Discoveries in the North.

[From our Nevada Correspondent.]

NEVADA, June 30, 1859.

There is considerable of a stir, hereabouts, concerning a great discovery up north, say sixty miles above Nevada. Many are leaving hourly. A party started from here last night about twelve o'clock, in order to overtake and head a preceding one. The account is that a lead has been discovered which can be traced for six miles, and all of it rich with gold and silver, and, by assay, will pay \$1,000 per ton. I have seen some of the specimens which look exceedingly rich for silver. It assays well, but whether the material as a whole will pay ten per cent, on what it is purported to yield, is a question yet to be determined. I need not say that it should not stir the equilibrium of your population. Several of my friends are on the road to fortune and if it is anything of importance, I will soon inform you of the fact.—COSMOS.

The succeeding letter gave more news, and was as follows,—to same paper:

JULY 8, 1859.

Agreeably to promise I forward the latest intelligence from the gold hunters of Washoe valley. Since the first company started, some weeks ago, companies of two and more have been departing, nightly as well as daily. A party has just returned, and have answered the question of "What's the news from Truckee?" which for some days past has been the leading question. It appears that in this excitement there is something substantial to back it. My informant states that there is plenty of gold and silver; that the few who have water to work are making several hundred dollars a day, and that a miner over there, in speaking of his claim said, "I only had water I believe I could fill my sluice half full of amalgam of gold and silver."

Two other letters were written to the *Bulletin*, bearing dates July 10, 1859, and July 17, 1859, and at different times up to October 16, 1859, from which letter I extract the following, which now has some interest.

OCTOBER 16, 1859.

The accounts first given were no doubt, deemed exaggerations but unlike other discoveries half was not told. Were I to transcribe the lines before me, respecting the value per ton, the estimated richness of the lead, the amount of money "in sight," you would say my correspondent (Geo. Hearst) was crazy, and myself not much saner. Prudence therefore dictates a more moderate recital, I think it is safe to say, however, that the two mines now being worked, have not ther equal in wealth and for the quantity of ore, on the globe. You will know of tons of silver and gold leaving here per month.

Thus, Mr. Editor, your correspondents have brought forth a little more data of the early history of that wonderful lode, the Comstock. Some philosophers say information is wealth. I certainly had information of great value soon enough to have reaped millions piled on millions. It was not my turn then. I have never sighed over it.

JOHN McAVIN, Jr., was killed at the Alaska, mine, Pike City, Sierra county, last week. He went down the shaft to repair the pump. The shaft is a three

compartment one, the cages being so arranged that while one is going down another is coming up. After McAvin had been below a few minutes the bell rang to hoist and the engineer started the cage on its upward journey. The cable had made but a few coils around the reel when the engineer noticed a sudden jarring and quivering of the rope which led him to suppose that something was wrong. He immediately stopped the cage and waited for another signal from the shaft. Not receiving the expected signal he hoisted the cage out of the mine, but seeing no one on it he at once summoned one of the other employees at the mine and lowered him into the shaft to ascertain what the difficulty was. When the opposite cage arrived at the surface it bore on it the almost lifeless body of the unfortunate young man.

MINERAL SPRINGS.—Secretary Teller, in the Pagosa Springs case, says: Many springs and many waters are impregnated with minerals held in solution; but it does not follow that the lands bearing such waters are mineral lands, and can be patented as such. Lands of a saline character are an exception, and are expressly provided for in the laws relating to the disposition of the public lands. Lands containing mineral springs not of a saline character are subject to sale under the general laws, and not under the acts relating to the sale of mineral lands.

A new camp has been struck by some prospectors from Calico, about 100 miles off in Inyo county. The camp is in Death Valley, on the edge of the Panamint range of mountains, and about forty miles from Panamint. Miners are already leaving Calico for that place, from which ore brought in assays \$386 in silver, and carries seventeen per cent. lead.

J. M. PASCOE writes from Calico district, California, to James Tickle, of Eureka, that miners' wages are \$3.50. Those who can lease mines are making money.

From March 7 to August 29, 1882, the Richmond Consolidated mine smelted 12,093 tons ore, yielding \$16,000, or a monthly average of \$102,000.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the demand
for these goods both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Grant and Old Abo Co., Black Hills also Corlies Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other appliances for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRANWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weighs 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

Reaction Hurdy Gurdy Water-Wheel.

This Wheel will be guaranteed to purchasers to give 8% of the theoretical power of water. Send for circular to L. A. PELTON, Nevada City, Nevada Co., Cal.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address,

ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 23, 1883.

Mr. A. B. Paul—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quick-silver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which slides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them. B. G. McLain, Superintendent Indian Spring Drift Mine.

BOONE & MILLER,

Attorneys & Counsellors-at-Law,

Rooms 7, 8 and 9.

No. 320 California Street, S. F.

(Over Wells Fargo & Co.'s Bank.)

Special Attention Paid to Patent Law.

N. B.—Mr. J. L. Boone, of the above firm, has been connected with the patent business for over 16 years, and devotes himself almost exclusively to patent litigation, and kindred branches.

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Glossary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commissions Codification, and gives many and improved forms. Price—Full law binding, extra paper, 680 pages, \$8.00. For Sale by DEWEY & CO., San Francisco.

FIGARI & RICHMOND'S BOILER AND TUBE COMPOUND.

We guarantee our COMPOUND to remove all scale and prevent any more being deposited. The COMPOUND forming a glazed surface on the iron, to which no scale will adhere and which preserves the iron.

The preparation is strictly vegetable, and is warranted to do all that is claimed for it without injury to the metal. Send for a circular.

274,689.—SCREW CLAMP FOR STOOLS.—A. Waugeman, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

NIPPERS FOR PILE DRIVERS.—Samuel Hadlock, Port Townsend, W. T. No. 274,189. Dated March 20, 1883. This improvement in nippers for pile drivers consists in a centrally hinged strut brace, pivoted at both ends, to and between the sides of the nippers, whereby said sides are held extended, to hold the jaws to their grip, and in a means for bending said brace centrally, to draw in, directly or indirectly, the sides to extend the jaws. It further consists in a peculiar extensible frame, constituting the nippers, in which said brace acts to the best advantage, and in a novel means for tripping the nippers. The object is to provide nippers which will effectively seize and sustain the weight, and will release it with certainty when desired, without the necessity of having one operator go upon the scaffold above. The common form of nippers is not certain in its action. Its jaws cannot be greased, on account of slipping, and consequently they have often to be pried off by an operator at the top of the machine. To constitute effective nippers, they should be certain in their grip, and readily disengaged.

COMBINED CUTTING, PUNCHING, AND TIRE-UPSETTING MACHINE.—Harris Morse, Tuttle-town, Tolueme county, Cal. No. 274,216. Dated March 20, 1883. This invention relates to a novel apparatus for use in blacksmiths' and other iron-working shops, and it consists in a combination within a single frame, of a tire-upsetting device, a cutting or shearing, and a punching device, and a drill-sharpening device. The whole of these devices are actuated by an oscillating or rocking shaft forming a double lever, and having movable boxes, by which it may be elevated or depressed. In combination with this movable shaft, the inventor employs a wedge-shaped sliding base, with rack and pinion for moving the same, so that the fulcrum may be raised or lowered, and thick plates cut or punched by successive movements.

RAILWAY SAFETY ALARM.—Wm. B. Morris, S. F. No. 274,635. Dated March 27, 1883. This safety alarm for railways consists in the arrangement of a series of levers at intervals in the section of a single track and normally held horizontally, tripping devices at each end of the series for releasing the levers and causing them to be elevated in the track, and devices on approaching locomotives for operating the tripping mechanism to raise the levers for subsequently depressing and re-adjusting them, and for coming in contact therewith while raised, to give warning. The object of the invention is to provide against the danger of collision upon section of single track, by giving notice at the further end of said section that a train has entered the other end.

SCREW CLAMP FOR STOOLS.—Randolph Waugeman, S. F. No. 274,680. Dated March 27, 1883. This clamp is intended to be put on screws of vertically-adjustable stools, chairs, etc., the object of which is to hold the screw tightly in the socket to prevent the side play or looseness, which is always attendant upon devices of this character. The invention consists in a wedge sleeve encircling the screw, which, either by its own weight, or by the downward pressure of the screw itself, is adapted to be depressed sufficiently in the standard and bind upon and clamp the screw so that it can not have any side play.

BOX FASTENER.—Stephen and Martin E. Martinelli, Watsonville, Cal. No. 273,863. Dated March 13, 1883. This improvement in packing boxes consists in the means of readily securing the cover to the box in such a manner that it may easily be removed without injuring the cover of the box.

PHYSICIANS say it combines all the desiderata of every ferruginous tonic prescribed by every school of medicine. Brown's Iron Bitters.

News in Brief.

THE President has gone on a short trip to Florida.

JOHN BROWN, the famous Scotch body-servant of Queen Victoria is dead.

THE coinage at the Philadelphia Mint in March aggregated 6,687,752 pieces, valued at \$1,114,073.

SOUTHERN UTAH is reported as having but little snow in the mountains, while the valleys are very dry.

WHEN the total losses by recent floods in the Ohio and Mississippi valleys have been approximated, \$30,000,000 will hardly cover it.

THE British returns for the financial year ending March 31st show that the revenue of Great Britain was £89,004,000; expenditures, £89,086,000.

FOR the past three months the importation of foreign dry goods at the port of New York amounted to \$39,404,403, against \$40,528,195 for the corresponding three months last year.

ONE hundred and fifty thousand acres have been sown to wheat and barley in Los Angeles, and there is a promise that the exportation of 1880 (11,000 tons of wheat) will be doubled, says the *Herald*.

THE Missouri Legislature has passed a bill providing that no railroad company in that State shall advance freights without giving twenty days' notice of the proposed change by posting the new schedule in three conspicuous places in each of its freight and passenger depots.

JOHN S. ENOS, Superintendent of the new Bureau of Labor Statistics, and his assistant, Hugh J. Mahon, have engaged rooms over the City of Paris, at the corner of Dupont and Geary streets, where they can be found between the hours of 9 A. M. and 5 P. M. each day. As the office is one of great importance to the laboring and mechanic portion of the community, it will require some time before the commissioners will be able to do anything practical, calculated to enlighten the masses on the relative rate of wages in the different parts of the country, etc.

PLAIN TRUTHS

The blood is the foundation of life, it circulates through every part of the body, and unless it is pure and rich, good health is impossible. If disease has entered the system the *only* sure and quick way to drive it out is to purify and enrich the blood.

These simple facts are well known, and the highest medical authorities agree that *nothing* but iron will restore the blood to its natural condition; and also that all the iron preparations hitherto made blacken the teeth, cause headache, and are otherwise injurious.

BROWN'S IRON BITTERS will thoroughly and quickly assimilate with the blood, purifying and strengthening it, and thus drive disease from any part of the system, and it will *not* blacken the teeth, cause headache or constipation, and is positively *not* injurious.

Saved his Child.

17 N. Eutaw St., Baltimore, Md.
Feb. 12, 1880.

Gents:—Upon the recommendation of a friend I tried Brown's IRON BITTERS as a tonic and restorative for my daughter, whom I was thoroughly convinced was wasting away with Consumption. Having lost three daughters by the terrible disease, under the care of eminent physicians, I was loth to believe that anything could arrest the progress of the disease, but, to my great surprise, before my daughter had taken one bottle of Brown's IRON BITTERS, she began to mend and now is quite restored to former health. A fifth daughter began to show signs of Consumption, and when the physician was consulted he quickly said, "Tonics were required," and when informed that the elder sister was taking Brown's IRON BITTERS, responded "that is a good tonic, take it."

ADORAM PHELPS.

BROWN'S IRON BITTERS effectually cures Dyspepsia, Indigestion and Weakness, and renders the greatest relief and benefit to persons suffering from such wasting diseases as Consumption, Kidney Complaints, etc.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

Cash in Advance.

Our terms are cash in advance for this paper. NEW NAMES will not be entered on our printed list until payment is made. Feb. 1, 1883.

THE ALBANY CYLINDER OIL

Has its globule undisturbed, stands a fire test of more than 500 degrees, is perfectly free from acids or oxygen, clings with more tenacity to the metal, and better resists the great pressure and heat of steam than any other lubricant.

"Challenge" Ore Feeders.

OVER 1100 HAVE BEEN IN SUCCESSFUL OPERATION.

Awarded First Premiums at the Preceding and last Industrial Fairs of the Mechanics' Institute of San Francisco.

TWENTY PER CENT. MORE ORE CRUSHED WITH FIFTEEN PER CENT. LESS WEAR OF IRON THAN BY THE OLD METHOD OF HAND-FEEDING.

The opposite cut illustrates the recently introduced G. P. and Spring Attachment, which replaces the Weight originally used, and result in an obvious improvement.

The practical operation of the large number of these machines now in use demonstrates the fact that the machine upon which a perfect Ore Feeder may be constructed is that of a carrier and not that of a weighing table. Uniform feeding is not possible upon the latter plan. The ore must be evenly carried upon a steady advancing plate or table to the line or point of discharge, and there be simply dropped. Jerky or spasmodically acting conveyances will not answer the purpose for feeding wet or sticky ores, nor for the ores of mines where they may change from sharp quartz to an iron ore material of quartz and iron ore matter.

The Ore Feeders are in Successful Practical Operation in the Following Quartz Mills, and are giving Perfect Satisfaction to their Managers.

P. O. Box, 1072. 320 Sansome Street, S. F.

LAND
Good land that will raise a crop every year. Over 12,000 acres for sale in lots to suit. Climate healthy. No drouths, had floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal.

THE ROLLER ORE FEEDER.

Patented May 28, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is a considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec 22, 1874; Sept. 2, 1879; April 27, 1880. Patent applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Timbering in Mines.—No. 7.

It is of course natural to seek to simplify the timbering in accordance with the conditions of the walls. These conditions are so variable that it is extremely difficult to indicate them, and we take a single example, for which we are indebted for details to Mr. Jourmaux, of Charlevoix, France, whose account is published in "Lectures on Exploration of Mines," by Durat. We translate as follows:

The most variable style of timbering is that applied in galleries or tunnels. Many of these galleries are very long, and serve as passages where tramways are laid on which to haul out ore or waste. In the French coal mines the ground, according to the conditions of the solidity of the roof, is sustained by the different means shown on the figures of the engravings presented herewith. This employment of dry stone, which is furnished by the work as it progresses, admits of important economy in the consumption of wood, since in the coal fields of France the consumption has been very heavy and wood is scarce. The engravings show the various means adopted in French coal mines, according to the character of the walls and roof.

In Fig. 1 the roof and walls are wanting in solidity; the frames are complete and the lagging more or less close in accordance with the nature of the walls. Fig. 3 is for the same conditions, with one sidewall firmer than the part which is supported by the timbering. Figs. 2 and 5 represent the condition of a solid roof, while the wall of the bed needs to be held by timbering or by walling up. Fig. 4 represents a schistose roof cut across the stratification, but as it has a tendency to "slack," it needs to be held up with a transverse timber. Finally, in Fig. 6, all the walls are solid. All these forms have been applied in practice.

THE DEBRIS CASE.—United States Circuit Judge, Lorenzo Sawyer, has overruled the demurrer to the bill in the case of Edward Woodruff *vs.* the North Bloomfield Gravel Mining Company *et. al.*, with leave to the defendants to answer on or before the next Court rule day—May 1st. The bill was brought against several

there was a separate and joint cause of action in each case. That the defendants, severally and jointly, co-operated and precipitated tailings into the streams long before the waters reach the valleys, where the nuisance complained of was reached, and that they operated together in producing the nuisance complained

Gold Discovery near Phoenix, Arizona.

[From our Traveling Correspondent, B. W. CROWELL.]

We now have a little gentle excitement right here in Phoenix. It is no less than a gold discovery, made public last Saturday evening, when W. N. Osborn and David Cling, came in showing fine gold bearing quartz, and assuring their friends that they had with the discoverers an interest in three claims just located, that they were assured from their small pannings would yield \$1.00 to the pound of ore. The claims are out about fourteen miles on Cave Creek road. The quartz is an out-crop, right out on the plains, 10 miles from water, and close to the main thoroughfare. If these parties are not greatly deceived in the initiatory showing, they probably have the outcropping of a real gold bonanza. From the small samples pounded and spooned it promised a yield of \$1,000 per ton. It is located in Magazine District, not far from John Osborn's old gold mine.

These first parties have located a strip 600 feet wide, by 4,500 feet in length, which they think covers the most of, if not all the ground that seems worth locating—yet some few are rushing out to do some prospecting in that vicinity.

"Old Probability," and several others, claim to have a long time known there would be rich claims located right there, or near there. Phoenix is a stirring stage and teaming center, twenty-eight miles from Maricopa, on the C. P. R. R., and the county seat

of Maricopa county. It is surrounded by well irrigated farming lands.

EXTRA EDITION.—We shall next week issue a twenty-four page edition of the MINING AND SCIENTIFIC PRESS, devoted more especially to the mining interests of Arizona. It will be fully illustrated and contain a large amount of matters of interest to the mining community.

METHODS OF TIMBERING AND WALLING IN GALLERIES.

hydraulic mining companies, severally owning mines at various points on the Yuba river and its tributaries, to restrain them from discharging the gravel, waste earth and mining debris, arising from working their mines, into the streams. Judge Sawyer, in a long decision, held, in effect, that the great damage alleged was multifarious, and that in the mining law

of. It was also held that any one of the parties in interest had a right to maintain an action without injury to other parties therein.

INFORMATION has been received at Candalaria that Mike Bonner, a former employe at the Northern Belle mine, perished on the desert between the terminus of the Carson and Colorado railroad and Calico mining district.

CORRESPONDENCE.

Notes From Eureka, Nevada.

(From Our Regular Correspondent).

EDITORS PRESS:—On Friday last, I visited the lava beds of the Eureka Con. Mine on Ruby Hill. Not a single Modoc did I encounter, but men of brawn and muscle were there. Armed with pick, shovel, hammer, drill, and gad, they were prospecting for ore in places where, years ago, the company did not think it worth their while; and in others that had been passed as useless to prospect in. This portion of Ruby Hill is being cut up and holed in every direction; old dumps are also being screened and assorted over for all that is in them which will pay to send to the furnaces. This work is being done by tributors, some of whom performed labor for a period of six months without making a dollar. Others however make strikes that pay them ordinary wages. When it happens that these tribute pitches prove very rich and extensive, it is understood by and between superintendent and the tributors, that the latter will surrender the pitch to the company, after having extracted sufficient ore to pay them for all the dead work that they have done towards the development of the ore body. Thus are others encouraged to persevere in the same manner, and on the same terms. At one of these places I found a chimney of ore five feet thick, that will work at the furnaces from \$60 up to \$150 per ton.

There is room enough in the unbroken ground in which it is incased to allow it to make into a body of considerable size and value. There are 130 men tributing in the Eureka Con. mine at present, the majority of whom are making less than \$1.25 per day. None of them are permitted to work on tribute where the superintendent thinks it will pay the company to employ miners at regular day wages. No place in the mine, as far as I went, from the surface down to the third level, is being left untried. Many of the old drifts, crosscuts, and winzes, that have been filled with waste rock are cleaned up, so that these openings may not be rendered useless by the tributors, who are permitted to stow away the debris in them for the time being, in order that they may put in their labor to the best advantage. It is also necessary to keep these places open to permit of proper inspection and thorough prospecting of the mine.

The Tributors

Are useful to the company, and there is not the least doubt that they can and do ferret out ore in places where it will not pay the company to hire men to do the dead work. They not only take chances on the smallest streaks, but often gouge into large bodies of low grade ore, of which there are many in the mine, and in them find chimneys that pay tributors to extract, when it will not pay the company to touch them. Why such bodies of ore are left standing in the mines, it is proper to explain. Ordinarily, large deposits of ore found in the Ruby Hill mines are of the least value near to the country rock, but the quantity of them improves as development is made. For instance, when one of these ore bodies is discovered, the portion of it nearest to the country rock may not carry more than four or five ounces of silver to the ton. After penetrating it for a distance of three or four feet, the value may increase to six, eight, or ten ounces. The next three or four feet may carry fifteen ounces of silver to each ton, and so on, until that portion of the deposit is reached which will pay the company to extract. Had the company extracted the ore from some of the immense chambers in the mine, taking all of the ore in them as it was found, by mixing the very low with the higher grades, they would have suffered a great loss. When the low grade ore left standing in the mine is prospected by tributors, it becomes necessary to allow them a liberal percentage to pay them for assorting it; otherwise a great quantity would be sent to the furnaces that it would not pay the company to smelt. The same rule obtains where rich ore is found by them in small veins, and the waste rock surrounding it is soft, or broken into small particles.

Running from the old Windsail shaft, on the third level, is a fair-looking fissure, in favorable ground. This, I learn, will be thoroughly prospected.

From the Compromise Line,

Which separates the Eureka Con. mine from the Richmond Company's, extending, as I am informed, from the 1st to the 5th level, and from the lava beds to the shale, is an immense block of ground, that hitherto has been considered unfavorable for ore. Drifts and cross-cuts have been driven through this at intervals, but they are so far apart that ore bodies of considerable size may exist in it. All this portion of the mine will now receive close attention, and the result may be gratifying to the stockholders.

The water has been increasing so rapidly in the Locan shaft during the past few days that progress on sinking was retarded. Work on it was suspended, but was resumed to-day. The water which was formerly pumped into the tank at the 600 foot station is now being lifted

to the surface, and, to facilitate the work, an additional boiler is being set in place. The increase of water is doubtless caused by storage in some of the large cavities existing in the country rock. These are drained by the hydraulic pump as quickly as possible, and cause only temporary inconvenience. As the readers of the MINING AND SCIENTIFIC PRESS will, no doubt, be glad to know how the Eureka Con. mine looks below the third level, I shall visit it again as soon as possible; probably during the week, and in time for description in my next letter. The

Mines on Adam's Hill

Are receiving rather more than ordinary attention at present. Several persons working under lease on some of them are meeting with very good success. Applications for tribute pitches were made to the owners of the Oriental and Belmont mine this morning by a party of Ruby Hill miners, but they were refused. I have inquiries made of me every day.

For Miners to Lease

On Prospect mountain, also on Silverado mountain, in Pinto district, and, if the present depression lasts, it seems probable at least that the mines outside of Ruby Hill will not sniffer by it. The Berryman Tunnel and Mining Company perfected their organization a few days ago, and commenced work on their claims on Silverado mountain this morning. Only local capital will be used at present. The work of development will be conducted with the closest economy. Not even the superintendent will receive payment for his services beyond regular miner's wages, and that he will have to earn as a practical miner by hard labor upon the ground.

At the Eureka Tunnel.

Miners have been bidding for contracts at almost starvation rates, and work upon the new engine shaft has been thrown up by them. This cannot go on, and the mine be worked, so a contract for sinking the next 50 feet of the shaft will be let to-morrow, upon more reasonable terms. The engine is in its place, and will be given steam as soon as the cable is placed on the reel. The ore veins above the first discovery chamber is running very irregular, and at present is making stronger at the south end than at the north. A nice vein of yellow carbonate ore in black oxides of manganese, is being followed from the 65 foot drift, north from the south winze, old works. No. 3 drift from bottom of same winze is in about 50 feet towards engine shaft; still looking well, but with no change. The Addison chamber underneath it, is still looking well, and producing ore, same as last reported. A track is being laid in the south drift, 105-foot level, to an incline winze, now down 75 feet. There is good carbonate ore at this point. There is but little change to note in other parts of the mine. The regular quantity of ore is being hauled to the furnaces.

Last month, 250 tons of ore was shipped from the Home Ticket Mine, to the Richmond furnaces. The quality of ore from this is improving to such an extent, that the owners of the Chipper Claim adjoining, will start to work sinking upon that property as soon as the snow disappears. Considerable discussion is being indulged in at present, in relation to the mines upon Home Ticket Hill, caused mainly by an article that appeared a few weeks ago in a west of England newspaper, a portion of which was copied in the *London Mining Journal* issued March 17th. The result, it is hoped, will be of benefit to Eureka district. M. H. JOSEPH.

Eureka, April 4th.

Como District, Nevada.

EDITORS PRESS:—There is nothing of interest to write concerning the Comstock mines. The work of opening out and exploring, is going on in the lower levels; from the 2500 to the 3100. What will be developed in the future, of course, cannot be told. The prospect thus far does not give much encouragement for the finding of ore bodies. There is being considerable low grade ore extracted from the upper levels of the Belcher, Crown Point, Kentuck, Yellow Jacket, Imperial Consolidated and Chollar. The Ophir company is also extracting some. C. C. Stevenson, having a lease of the Lower Comstock and Royal mine (at Silver City), after having been to much expense to clear the mine of water, has about succeeded and is prepared to prospect for ore, which he will doubtless find and extract. Mr. Stevenson has the knack of finding ore generally, when he goes after it; therefore he is a good man for the community, as he puts considerable money in circulation, paid to employees at the mine, and his mills where he reduces the ore. Teamsters also get their share for carting the ore. There is also the money paid out for supplies for the mines and mills. All of which is of much benefit, and highly appreciated these dull times. You have heard much of

Como and Palmyra,

Situate about twenty miles from this place. Indications of mines existing there were discovered as early as 1862. In 1863 and 1864 there was considerable excitement in regard to the mine, which took quite a population up there, consisting of miners, traders, saloon keepers, gamblers, and loafers, and much was said of the Como mine. The excitement was kept up until John B. Winters built a mill there, as there

had been none put up nearer than the vicinity of Dayton, some fourteen miles off. Quite a number of tons of ore were reduced at the Winters mill, but it seems that it did not yield equal to expectation, which threw a damper on the whole camp, causing a great stampede, leaving it almost deserted. It has remained so ever since, with the exception of about three years ago, some miners went up there, and went to work to relocate the old locations, and do prospecting work on them. They reported their prospects good, and others went, carrying with them the followers to all new mining camps. The Eureka company seemed to be the most lucky one, for they sunk a shaft to a depth of 70 feet, and took out considerable ore. They made so good a showing that a Mr. Walter made a contract with them to the effect that if the company would furnish him with a certain quantity of ore at a stated price, he would put up a mill and reduce their ore. He erected a five stamp mill, and a hoarding-house for his employees. He ran quite a number of tons of ore through his mill, but it did not pay, although it assayed well. Why the yield of the mill was not better, I do not know, unless the ore was not properly handled, and most of the gold and silver was lost. The men interested in the mine were all poor, and had to discontinue work. They had not the means for putting up the necessary works to carry it on, therefore were compelled to stop. At no time from the first discovery of precious metal ores at Como and Palmyra had capitalists gone there and expended an amount of money sufficient to open and develop a mine. Everything that was done was done by poor men, who had the faith, but not the means to develop the mine. I lately visited the place to see for myself what was the

Cause of the Failures

To develop a prosperous mining camp where there had been so much ore found that gave good assays. I at once saw what seemed to me to be the trouble. The mines are of such a nature that capital is required to open and develop them. There is but little cropping at the surface, therefore men with nothing but muscle were powerless to succeed. The distance to water is but short, and when that was encountered work had to cease. When a depth was attained that the hoisting could not be well done by a windlass, the shaft had to be abandoned. The ore is free milling, and there is no reason why the silver and gold cannot be saved if properly handled. The assays show that the ore yields two thirds gold and one third silver. The Eureka G. & S. M. Co. is

The Only Company Now Operating

There. They have expended about \$25,000 on the mine since they commenced work. Having worked down with a whipsaw, until water was encountered, they commenced a new three compartment shaft and carried down two compartments to a depth of 200 feet, with a sump below. The shaft is well timbered, and is a good one. They have out on the dump from forty to fifty tons of ore taken out of the old shaft, which it is thought will yield \$100 per ton. The vein, as shown by the different workings, is 125 feet in width. There is a steam pump in the new shaft which takes out the water and keeps the mine drained. At the bottom of the shaft a spacious station was cut out and timbered, from which a drift was started west towards the vein, sixty feet distant. At the time I was there the east wall of the vein was reached and cut through, showing quartz, clay and porphyry mixed together. The quartz gives good assays; and when a little more advance is made in the vein, a better opinion can be formed of its value. I examined it closely where the opening was made and found it to be exactly similar to the Comstock. The material composing it is the same as is found here where paying ore is found. I see no reason why the company will not develop a good mine. There are certainly all of the characteristics required, to warrant the belief that a valuable and permanent mine will be developed. It may be that a cross drift through the vein will determine the matter, and it is the intention of the Superintendent to carry it through to the west wall, a distance of 125 feet. They have in their hoiler and engines plenty of power to do the hoisting to a depth of 1,200 or 1,500 feet. The company purchased the machinery, galloons frame, building, cars, wire rope, &c., from the Europa Company of this place, and have a good outfit for opening and working the mine, which they seem determined to do. Mr. H. L. Symons is acting as Superintendent, and has been, and is, carrying on the work with economy and much mining skill. He has taken the proper course to develop the mine, and with much economy, and is convinced that he will be successful in opening one that will be very valuable. The cross-drift through the vein at the 200 level may be the means of determining the question of its being a good permanent mine, without being obliged to wait until a greater depth is attained. I am of the opinion that if the vein was narrow and the ore consequently more concentrated, it would be much better than it is. Of course future workings will determine that.

The kind and character of the formation in the Como district, was a surprise to me. I found it much more favorable for mines than I had expected. As the Eureka Company have the means and the faith, I suppose that they will go on and demonstrate the fact, that they have a valuable mine or not, which will decide the fate of the camp. JAMES DELAVAN.

Virginia, Nev., March 30.

Spring Valley Mines.

The Eagle mine, at Spring Valley, one of a number owned by the Vandewater G. & S. M. Co., a New York corporation, is being worked under the supervision of Major E. D. Luxton, and is producing sufficient ore to run the company's fifteen-stamp mill steadily. The company employs thirty men at the mines and mill, and every one of them, from superintendent down, work at something about the premises. The mill is running on gold-bearing quartz from the Eagle mine, and is paying the expense of mining and milling as well as that of developing the company's mines. A double compartment shaft is being sunk on the Vandewater mine, which adjoins the Eagle on the east. It is designed to sink this shaft to a depth of 400 feet, and then run levels along the lead into the Vandewater and Eagle ground. Some very fine silver ore is being found on the Vandewater as well as in the lower works on the Eagle; while west of the Eagle, on the Troy lead, also owned by the company, galena ore, carrying gold and silver in paying quantities, has been found.

When the bodies of silver ore known to exist in the Vandewater are developed, improved machinery will be put in the mill, which is now run on gold ore exclusively, to reduce and amalgamate it. Some trouble has heretofore been experienced from a scarcity of water in the fall, but this will be overcome when the shaft is sunk, as that will furnish water for milling purposes at all seasons of the year. The ledge, which has been opened at one point on the Eagle to a depth of 212 feet, is one of the best defined in the State, and there is no question as to its permanency. It is expected that very rich bodies of gold-bearing quartz will be found in the mine, as the gulches below it have been worked for years for placer gold, and have produced, as nearly as can be ascertained, about a million dollars in gold dust. Chinese are yet at work in the diggings, and notwithstanding the great scarcity of water, manage to make wages. With the example of the Arizona mine before him, the superintendent hopes to be able to convince the company that the true policy in mining is to prospect ahead at all times, so that when there is a fault or a barren place in the lead, mills will not have to stop for want of ore, and the mine will not be condemned as worthless, as in the case of the Arizona, which although it yielded millions, was closed down when a non-productive zone was reached, while beyond it, as has since been demonstrated, large and rich ore bodies exist. It is the opinion of experienced mining men that the expenditure of a few thousand dollars in sinking the shaft already commenced on the Vandewater Company's mines, and running levels on the lead from that shaft, will develop one of the most valuable mining properties in the State.—*Silver State*.

The Lake Valley Mines.

The *Leader* says that a letter from an old Eureka, now at Lake Valley, to a gentleman at Eureka gives the following regarding that country: The mines are described as being very shallow, all of the ore being near the top. That which is found, however, is very rich, going as high as \$2,000 per ton. An Eastern company owns everything that is worth owning. It has one furnace, which runs but a portion of the time, as the ore is not found in sufficient quantities to keep it going. Two "cupels" have been erected, but are a failure, and but one at a time is put in operation, as they do not stand the test for more than twenty-four hours.

The writer states that there are a number of Eureka men there who could build good ones, but for some reason or other the company will not permit them to make a trial. He advises his friends not to go there, as there is no money in the place and wages are very low. Miners get \$3 a day; and are compelled to work ten hours; furnace hands, \$3 and \$3.50 per day, according to their merits; engineers, \$4 per day of twelve hours; and chief smelters, \$4. Board costs \$8 per week, and, as the correspondent says, "d—d poor at that."

The climate is described as being nice enough, and the country a pleasant one to live in, but as for money-making, that is out of the question. Everything is slow-going, the place overrun with all classes of people seeking employment, and, all in all, a good place—to stay away from.

A CHANCE FOR A MILL MAN.—A practical mill man with a little capital is needed here. Should such a man choose to avail himself of the opportunity presented, he will find a large return for the money invested. Should a mill be erected about one half a mile south of the lake, on the line of the railroad, where abundance of good water can be had at a depth of not more than thirty feet, and where wood can be easily obtained, it would draw custom from the mines on Mount Grant, Mount Cory and the canyons south; also from Santa Fe and the numerous other districts in that direction. Ores that are now shipped to San Francisco for reduction would be worked here, to save cost of transportation; and owing to the great number of claims from which small quantities of ore are being taken and the great variety of ores, there is no question about a reduction works situated at this point, which is centrally located in respect to so many of the districts, doing a profitable business for years to come.—*Northwestern Bulletin*.

MECHANICAL PROGRESS.

Masonry—Ancient and Modern.

Masonry is the art of arranging stone or brick in proper form so as to produce a regular construction; the term is popularly applied to stone-work, however, in contradistinction to brick-work, which is generally employed with reference to the use of brick.

The masonry of the ancient Egyptians was remarkable for the large size of the stones employed, sometimes as much as thirty feet in length. They were laid without mortar.

The Cyclopean or earlier masonry of the Greeks, some remains of which exist in the walls of Mycenae and Tiryns, was formed of large and irregularly shaped masses of stone, the interstices being filled with smaller stones. Tyrrhenian or Etruscan masonry is also composed of similar stones, but so fitted together as not to admit of smaller stones between them. The more ancient remains of Greece and Italy afford examples of this kind of masonry. Peru also affords remarkable instances of Cyclopean masonry.

To this succeeded the practice of making the beds horizontal or nearly so, but the vertical joints were irregular. All the preceding were laid without mortar. The Phœnician ashlar masonry is known by its bevel, and the specimens uncovered at Jerusalem are of surpassing interest.

The Greeks and Romans used several methods for walling, as the *opus incertum*, formed of square stones laid horizontally, the interior being of small stones; the *opus recticulatum*, composed of square stones laid diagonally; *isodomon*, in which the courses were of equal height; *pseudoisodomon*, in which they were unequal; *Greek implectum*, formed altogether of coursed work, and Roman *implectum*, of coursed work on the outside, the interior being of rubble. In these the stones were small and laid in mortar. Where large stones were used, no mortar was employed. The Roman *implectum* found in England has sometimes courses of tiles built in.

In a few of the earlier English buildings, considered by some to be Saxon, the quoins, the door and window jambs, and occasionally some other parts, were formed of stones alternately laid flat and set up endwise; the latter were usually much longer than the others. This is termed long and short work. In the Norman period, herring bone work, consisting of stones laid endwise in an oblique direction, with alternate courses laid horizontally, was frequently employed in rubble walls.

The stones used during the middle ages were seldom larger than could be lifted by two or three men.

Modern Masonry.

The various kinds of masonry employed in modern practice, may be divided into three principal classes: Rubble work, in which the stones are not squared; coursed work, in which the stones are squared more or less, and set in courses; and ashlar, when each stone is squared and dressed to give dimensions. Some of these kinds are used conjointly, as rubble with cut stone plinth, quoins, piers and coping; ashlar facing filled in with rubble, etc.

The largest stones ever placed in a wall by the hand of man are probably those in the foundations of the temple of Baalbek. Thompson says:

"The first tier above ground consists of stones of different lengths, but all above twelve feet thick, and the same in width. Then come three stones, each more than sixty-three feet long. One of them lies in the quarry, where it can be viewed all round, and measured easily. It is fourteen by sixteen, and sixty-nine feet long. It is one and one half miles distant from the temple." The stones are so well laid and jointed, that it is difficult to find the crack, which, indeed, will not admit the blade of a knife. Dr. Thompson says he quite overlooked it at first, and supposed the stone to be 120 feet long.

The foundation is much older than the Greek temple which was built upon it and occupies a portion of the area. The stones of the former building are believed to have been cut up to form the shafts, capitals, etc., of the Corinthian temple subsequently built. The original was probably the work of that Great Asiatic nation of which the Phœnician people was an outlying branch, and possibly Arabia the home.

The term monolith is applied to a structure consisting of a single column or block. Also to such erections as the obelisks of Egypt, some of which are now in Rome, Paris, London, and New York. The term monolith is likewise applied to structures in which the blocks are immense, in some cases reaching from the foundation to the entablature, as in the United States Treasury at Washington. This building is said to have larger stones than any used in the pyramids of Egypt, and to be a more massive construction in respect of the size of its stones than any other building in the world, except the church of St. Isaac, at St. Petersburg, Russia.

The Largest Monolithic Temple.

In Egypt is that of Tel-el-mai; on the Delta. It is twenty-one feet nine inches high, thirteen feet broad and eleven feet seven inches deep. This size is much exceeded by the dimensions given by Herodotus of the temples of Amasis and Latona, which were also, we are informed, on the Delta. The former one, he states, required three years to transport, with the aid of 2,000 labor-

ers, from Elephantine to Saïs, a distance ordinary of twenty days Nilotic navigation. The temple of Latona was still larger. "The most wonderful thing," says Herodotus, "that was actually to be seen about this temple was a chapel in the inclosure made of a single stone, the length and height of which were the same, each wall being forty cubits square (60 feet), and the whole a single block. Another block of stone formed the roof and projected at the eaves to the extent of four cubits." According to the measurements, supposing the walls to have been only six feet thick, and the material granite, as in all other monoliths, this monument would weigh 7,000 tons, being 76,032 cubic feet, without the cornice, which was placed on the roof. This capstone would weigh 2,400 tons, if six feet be taken for its thickness.

Progress of the Steam Boiler.

Mr. John Whitelaw recently read an interesting paper before the Civil Engineers' Club of Cleveland, Ohio, showing the gradual progress which had been made in the duty of steam engines during the last 100 years, from which we collate as follows:

In this country, the duty of a pumping engine is estimated by the number of pounds of water raised one foot high on a consumption of 100 pounds of coal. Thus the record of pumping engines is stated to be a certain number of pounds of water raised one foot high for each 100 pounds of coal burned.

The present results show remarkable gains over the old-time engines. In 1770, Jonathan Hornblower and John Nancarrow were the most noted builders of pumping engines. The best average duty which they were able to get from 100 pounds of coal was, in round numbers, 6,000,000 foot pounds. The present engine does more than sixteen times as much work for the same fuel as the old style of machines. These were vacuum engines. Steam was only used to make a vacuum, and thus generating power. James Watt's improvements followed, and in 1793 he had so far improved the steam engine that his best machine made an average duty of 27,000,000 foot pounds per 100 pounds of coal. The engines now in use at Lynn, Mass., do about four times better than that. Watt, in his time, pronounced his engine perfect, and said that no further improvement could be expected.

In 1814 Arthur Woolf made engines that showed a duty of 34,000,000 foot pounds; and in one example a duty of 72,000,000 was reported.

In 1828 Capt. Grose made improvements on his engine, and the duty was found to be a little over 87,000,000 pounds.

In 1834 William West produced an engine that yielded a duty of close on to 99,000,000 of pounds.

In 1840 Hocking and Loam extended the expansion principle, and in 1842 one of their engines showed a duty of 107,000,000 pounds—a result that is hard to beat at the present time.

The boiler engineering and firing of the old time was very peculiar. Instead of increasing the number of boilers when more steam was required, they used to have one boiler of gigantic dimensions, with correspondingly large fire-place. They also placed the fire bars eight or ten feet below the bottom of the boiler, and then filled up the space with coal. They thought the more coal they burned the more steam they would get. A boiler at Daletholm mine was twenty-four feet in diameter and twenty-four feet high. The furnace was seven feet below the bottom of the boiler, was nine feet wide, and extended from one side of the boiler to the other. Trevithick said the fire in this boiler was seven feet thick, and had in it thirty tons of coal.

SOLID AND HOLLOW IRON COLUMNS.—A confusion of ideas is sometimes found among practical men respecting the comparative strength of solid and hollow pillars. One hears it often said, says the *Building News*, that a hollow pillar is stronger than a solid one. Now this is, as an able authority has pointed out, not absolutely the case; it is perfectly true, that, comparing the strengths of two pillars of the same height and diameter, one solid and the other hollow, the latter has the advantage of being economically stronger. The fact is, the solid column is stronger than the hollow of the same external diameter; but the lesser area is more effective than the greater, because the central portions of the solid pillar are less useful in resisting the bending force than the metal in the circumference of the hollow pillar. But if the quantity of material in both the solid and hollow pillar of equal height is the same, the hollow pillar is by far the stronger. A simple geometrical construction will enable any one to understand this fact, by enabling us to proportion a hollow column of the same area as that of a solid one, by one of the diameters being given.

It is shown, in fact, that hollow columns of the same area of metal as a solid one may be made to any larger diameter, their strengths increasing proportionately till a limit is reached by the shell of the metal becoming too thin to insure a sound casting. Taking an example from Downing's work, a hollow pillar nine inches in external diameter, having an internal diameter of 8.062 inches, and a thickness of metal of 0.47 inch, or about one half inch, is five and one half times stronger than a solid pillar with the same quantity of metal. A thickness of one half inch may be regarded as a practical limit in manufacture.

SCIENTIFIC PROGRESS.

Long Distance Telephoning.

That the telephone will soon almost entirely supplant the telegraph, even for long distances, is quite a matter of certainty. In many places, even now, it is common to use the telephone for all distances for twenty-five to seventy-five miles or more. Experiments are now being made at the east to show the practicability of the telephone for hundreds of miles.

A notable experiment in long distance telephoning was recently made on the new compound steel-copper wire of the Postal Telegraph Company, lately completed between New York and Cleveland, Ohio, a stretch of 650 miles.

The compound wire has a diameter of seven thirty-seconds of an inch, consists of a steel core, weighing 200 pounds per mile, that will resist a tensile strain of 1,650 pounds, on which copper is deposited to the extent of 500 pounds per mile. The wire has seven times greater conductivity than iron wire of equal size, copper being the best conductor known except silver. It has double the tensile strength of iron wire, or equal weight when strung on the lines, will last longer, permits the use of low tension currents and small batteries.

Ninety per cent. of the wires now in use are No. 9 iron with a resistance of 20 units per mile, and the very best are No. 6 with a resistance of 10 units, while the compound wire to be used by this company has a resistance of only one and seven tenths units. The resistance of No. 9 iron wire on a line from New York to Chicago, 1,000 miles, is over 20,000 units, and on a No. 6 iron wire over 10,000 units, and on the compound wire less than 1,700 units, thus bringing Chicago telegraphically as near to New York as Philadelphia; and San Francisco as near as Cleveland, compared with the best wires now in use.

When the two compound wires are completed between New York and Chicago, their operating capacity will, it is said, be thirty thousand messages per day.

The new conducting wire is certainly a great improvement over any land line of similar length heretofore established, and its successful completion marks the opening of a new era in the progress of electrical communication.

The new wire with its accompanying improved transmitter is likely to revolutionize the telegraphic service of the world by leading the way to the substitution of easy, economical, and scientific lines and modes of working in place of the present systems, which, by comparison, are difficult, costly to operate, and unscientific.

The ordinary electric telegraph has become altogether too old and clumsy. The progressiveness of the age demands some improvements on an institution which is now nearly a half century old. Fifty years is too long to stand still, and now we are soon to have the telephone for all distances. The human voice will soon traverse the ocean as well as the land, and America will talk to Europe *à la vue*.

Hearing in Insects.

The sense of hearing in insects has recently been carefully studied by Herr Gruber. According to an English journal, that scientist has found the common cockroach to be very sensitive to music. On sounding a violin note when a cockroach was running across the floor, the insect would suddenly stop. When a number of those insects were placed in a glass vessel, on making a strong sound near them, they manifested great agitation and excitement; some would even fall down from the sides of the glass, as if paralyzed. When one of them was hung by a thread attached to its hind leg, and when quiet, if a bow was drawn sharply over the violin strings, at a distance of four or five feet, the insect would be greatly excited, and struggle frantically to get its head uppermost.

Beetles were also similarly affected by sounds, but grubs and ants gave no certain indications. Of aquatic insects, various kinds of *corixæ* were tried. These would often remain very quiet for a time, but, on tapping the glass with a glass tube, they would rush about with great agitation.

A disk at the end of a long rod, drawn to and fro in the water near a quiet *corixa*, produced no effect; but by conveying the sound of a struck bell into the liquid by the rod, there was a lively reaction; similarly when a howl drawn across a glass bell was brought in contact with the water. These creatures were also sensitive to high violin notes in the air, and to the sound of a metal plate struck by a hammer, etc.

Still more sensitive were various aquatic beetles. On the other hand, various larvae, especially ephemerides, were unaffected; but these were sensitive to mechanical agitation of the water. Herr Gruber considers the response the insects make to sound an indication of their hearing, and not mere reflex action.

THE USE OF GAS FOR HEATING AND POWER.

Dr. C. Siemens predicts a vast extension of the consumption of gas in the future for heating and power. It will effectually dispose of the smoke nuisance, and will afford in time a more economical and convenient fuel. When heating gas is supplied to us from street mains at twenty-five cents per 1,000 feet, as it will be at some time in the near future, the housekeeper's millenium will not be far off.

Primeval Celtic Map Stones.

In many parts of Switzerland are often found smooth, flat stones, evidently hand-polished, and covered with dots, lines, circles, and half circles. The origin and use of these stones, known among country people as *Schalensteine*, has long been moot point among the learned. Some have thought they were charms, others that they were meant to commemorate the dead, or that the signs on them were undecipherable hieroglyphics; but it has been reserved for Herr Rodiger, of Bellach, in Solothurn, to throw a new light on these mysterious relics of the past, and suggest a theory concerning them which seems to meet all the necessities of the case. The *Schalensteine*, he says, are neither more nor less than topographical charts, as a comparison of them with any modern map of the districts in which they are found will show. The engraved dots correspond with existing towns and villages, the lines with roads. Even the fords and mountain passes are indicated. Herr Rodiger has examined many of these stones from various parts of the country, and he possesses a collection, picked up in Solothurn, which form together a map of the entire canton. Another significant circumstance is that the *Schalensteine* are mostly found at intervals of about two hours (say, six miles) from each other, and at spots where several roads meet. The former, Herr Rodiger calls "headstones" (*Hauptsteine*), the latter he designates "by-stones" (*Nebensteine*). If he be right in his hypothesis, the places where these stones are met with possessed considerable populations long before the dawn of history; even the villages shown on the *Schalensteine* must be far older than the Christian era. Herr Rodiger considers the Swiss map stones to be of the same origin as the similar stones which are found in Germany, Scandinavia, India and further Asia, and sees in them another proof of the high antiquity and common origin of the Indo-Germanic races, and the existence among the latter, in an indefinitely remote age, of civilized habits, organized trade, and more culture than is generally supposed.

RAREFIED AIR AS A CONDUCTOR OF ELECTRICITY.—Edlund continues his researches upon this subject. A number of experiments are described to show that the phenomena of the opposition to the passage of sparks from terminal to terminal in rarefied air cannot be explained by the theory that a vacuum does not conduct electricity. He carefully discusses the question of the contrary electro-motive force which is developed at the terminals. "It is not the resistance of the gas but this electro-motive force, increasing with the rarefaction and connected with the electrodes, that presents an obstacle to the passage of the current. Everything is in favor of the hypothesis that vacuum opposes a very feeble resistance to the propagation of electricity." Without the employment of electrodes, one can excite an induction current in a Geissler tube, which is sufficient to produce light. This would be impossible if the highly rarefied gas or vacuum were an insulator.—*Phil. Mag.*

SUDDEN DESTRUCTION OF MARINE ANIMALS. In the *Geological Magazine*, Professor T. Rupert Jones accounts for the manner in which large numbers of marine animals have, in past ages, suddenly perished in their own element and become entombed: 1. (fishes) by either usual or periodical influx of fresh water from the land; 2. by volcanic agency; 3. by earthquake waves; 4. by storm; 5. by submergence, when massed together in frightened shoals, or when burrowing in sand or mud and accidentally buried by other sand and mud; 6. by being driven ashore by fishes of prey; 7. (fishes and mollusks) by too much and too little heat in shallow water; 8. by frost; 9. (fishes) diseases and parasites; 10. (fishes and mollusks) miscellaneous causes, such as ferruginous springs, poison, lightning, etc.

ELECTRICAL LIGHT OF COMETS.—According to Huggins, comets emit a characteristic light, which indicates, by special analysis, the presence of carbon, hydrogen and nitrogen, elements which are shown by the spectra of acetylene and cyanhydric acid. Berthelot thinks that these results point to an electric origin of the light. He has shown that acetylene is formed immediately and necessarily, whenever carbon and hydrogen come under the influence of the electric arc. When nitrogen is added to acetylene, the electric influence produces cyanhydric acid. It seems scarcely possible to conceive of a continuous combustion in cometary matter, but an electric illumination may be easily understood.—*Ann. de Chim.*

COMMON GEOLOGICAL TERMS AND COLORS.—At the Geological Congress, held in Bologna, the precise meaning to be given to words used in descriptive geology was determined, and a common scale of colors for geological maps was adopted. It was also resolved to prepare and issue a geological map of Europe on a large scale, at a cost of \$12,500, to meet which the Governments of Europe are expected to contribute.

A COMET REAPPEARS.—A cable message announces the discovery of D'Arrest's comet, by Dr. E. Hartwig of the Strasbourg Observatory. He predicted the discovery about April 23d. This comet was first discovered by D'Arrest at Leipsic, in 1851. It was observed again in 1857-8 and in 1870.

Mining Share Market.

Our stock tables above give what few fluctuations have occurred in mining stocks the past week. The only peculiar feature of interest has been the rescindment of the dividend of the Yellow Jacket Company. On the 4th inst. the company declared a dividend of twenty cents per share. Now, the trustees of the Yellow Jacket have rescinded the dividend, under the advice of the attorney of the company, who is of the opinion that the money in the treasury cannot be appropriated for dividend purposes, because it does not come clearly under the head of net earnings, from which dividends are only permitted by the statutes of Nevada, the Yellow Jacket being a Nevada corporation. This is the second time that the Yellow Jacket trustees have taken such action. It was in April, 1869, that the Board declared a dividend of five dollars per share, but a fire occurring in the mine soon after, the dividend was rescinded. The company had just paid three dividends in January, February and March, the same aggregating \$360,000. In January, 1869, the mine sold at \$1,375 to \$1,610 per foot. In the following February sales were made by the share. There was then 24,000 shares in the mine, and the first sale under the new system was \$77 per share. Since then the stock has increased to 120,000 shares. The dividend rescinded fourteen years ago this month, was followed three months later by an assessment of ten dollars per share, or \$240,000.

At the north end of the Comstock all the money expended is being placed where it will do the most good, and the prospecting done is being carried on at points where there is the greatest likelihood of striking something. This is, of course, gratifying to assessment-paying stockholders, who very naturally wish to see their money judiciously expended.

From the Gold Hill mines a large amount of low-grade ore is being extracted, and the aggregate is considerably increased by the yield from the Chollar croppings.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Richmond, April 4th, \$18,235; Hanauer, 3d, \$3,200; Ontario, 3d, \$3,842; Horn Silver, 3d, \$1,800; Stormont, 4th, \$3,430; Silver Reef (for March), \$45,411; Hanauer, 5th, \$1,750; Stormont, 5th, \$2,700; Ontario, 5th, \$1,303; Horn Silver, 5th, \$12,000; Lexington (for March), \$9,700; Hanauer, 6th, \$1,780; Ontario, 6th, \$4,360; Horn Silver, 6th, \$9,000; Bullionville, 8th, \$7,735; Horn Silver, 8th, \$12,000; Ontario, 8th, \$6,480; Northern Belle, 6th, \$7,099.17; Bodie, 9th, \$4,270; Bullion, 10th, \$1,900; Contention Con, 6th, \$55,488; Christy, 5th, \$2,490; Betty O'Neal, 6th, \$3,765, 9th, \$3,379; Mt. Diablo, 6th, \$5,097.95; Martin White, 4th, \$2,245.76; Northern Belle, 3d, \$17,045.59; Navajo, 9th, \$16,400; Odessa, 3d, \$4,128.50; Standard, 2d, \$10,484.77; Yellow Jacket, 4th, \$18,379.81; Pinal Con, 27th to 2d, \$7,636.29.

DYSPEPSIA, heart-burn, nausea, indigestion, etc., are always relieved by Brown's Iron Bitters.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

DRYTOWN.—Amador Ledger, April 7: We learn that the mining outlook in the vicinity of Drytown is very encouraging at the present time. The Seaton mine is looking unusually well, and the Loyal lead and the Potosi mines, which have been idle for some time, will soon resume operations. The Loyal will start up next week and the Potosi in about a month.

BUNKER HILL.—It is pleasing to be able to report continued improvement in this mine. A body of ore has been encountered on the foot wall, which promises to lift the company out of debt in time. The ledge is said to be 10 ft wide; the milling portion of it we understand, is from 5 ft to 6 ft in width. By working only this pay rock, which at the lowest estimate is expected to yield \$6 per ton, a fair profit can be realized. Ten stamps of the mill, were in operation in the early part of the week, with the prospect of the number being increased to 20 in a short time. From 15 to 20 men are employed, and the force is being rapidly increased.

MISCELLANEOUS.—Rock is being hauled from the Vaughn mine to the Kelly mill, which will be started up in a few days. The rock in the Morgan tunnel continues to look well.

UPPER RANCHERIA.—Times have been very dull with us on account of the dry weather. The miners have done nothing all winter, and the farmers have been grubbing and growing; but the past few days their contentances have been somewhat changed on account of the rain, the blessed rain; and we will not complain any more now, if it rains till the Fourth of July. The miners will not get to do a great deal as the rainy season is so near over. The Blue gravel company commenced piling last Wednesday. The Hancock company also commenced operations last Tuesday. George Evans and brother have not done anything on their claim yet; are waiting for water to get through the Volcano ditch. These three mines are looking well, and prospect well, and would pay handsomely if water could be procured to work them the year around.

BUTTE.

HELLTOWN MINING SCHEME.—Butte Record, April 7: Pres. Longley, one of the oldest and best known miners on Butte creek, was in Chico the other day, and in speaking of the claims said that not much gold had been taken out during the past year, because of the scarcity of water to work with. There has been enough rain, but as there was no way to confine it, it all ran off into little mountain streams before any use could be made of it. Mr. Longley says that there is untold fortunes in the golden metal hidden away in the bowels of the earth about Helltown, but the miners are powerless to reach it. They are poor, and cannot convey water to the proper spot. Several years ago large sums of money were spent in building the Shepherd ditch, which tapped Butte creek for the purpose of carrying water into the claims. For a time this enterprise proved of vast value, but it was not properly constructed, one of its faults being that it was dug too deep, and now it was almost abandoned. Mr. Longley said that an effort was being made by the miners to induce some capitalists to construct a flume or ditch to take water from old Butte creek to their mines. The intention is to take their stream from the head waters of Butte creek, some 20 miles away. It would cost a little over \$1,000 per mile to build a flume but the miners feel confident of striking a rich deposit, as it is a well-known fact that the Helltown hills are filled with the purest gold.

CALAVERAS.

HURT.—Mt. Echo, April 5: Henry Kirkpatrick, a miner employed in the Gold Cliff mine near Angels received several severe cuts on the head by falling stones, on Saturday last. It appears that he was working under a bank some 30 ft high, when a small cave took place at the top of the bank. Mr. Kirkpatrick saw his danger and attempted to run out of the way, but was struck by a sharp stone of several pounds weight, and injured as above described. Dr. Baker dressed his wounds, and he is doing as well as could be expected. Perhaps the richest strike but one in this county within the past 20 years, was made on Tuesday last by George Osborn and son in the Gold Hill mine some two miles west of this town. This mine was first discovered about 26 years ago, and there have been large sums taken out from time to time; but the late discovery is the richest of all. A specimen of the gold taken out on Tuesday was exhibited at our office the same day, the weight of which was about 12 ounces. It is reported that \$2,000 was taken out in one hour on the day of the discovery and that thousands of dollars were still in sight. In fact, it is simply immense. A further description will be given next week.

MURPHYS.—James Moss has just made a run of 20 tons of quartz from the Eddie Dewitt mine, which is a property belonging to your humble correspondent. As there was much speculation in regard to its worth, and as the inert brain of street corner experts, quartz sharps, etc., were unduly exercised in the momentous question. I thought it my duty to make a public statement and relieve the strain on the afore-said experts, etc. The gold for the most part was very fine, and, of course, much of it escaped; as was proven by assay of the tailings. Mr. Moss stated that in all his experience he never made a run where there was so much extremely fine flour gold saved. The rock paid a trifle over \$8 per ton in full gold; tailings asaying \$12 per ton, makes the rock worth \$20 per ton by the Oro Plata Co.'s process. This must be the minimum rate; for the sulphurets by stamp treatment are pulverized so fine that much of it escapes on the surface of the water. Here is an argument in favor of pulverizers. We earnestly hope that this result so satisfactory to me, may be so to the curious; and that the wheels of our little but mighty world may be set in motion again. The Boston Co.'s mill is running steady on Red Wing ore with good results. The capacity of the chlorine works is pushed to its utmost capacity in treating the second class concentration. The first class concentration of which a number of tons are saved and which assays in the thousands, are reserved for special treatment. Another pulverizer will soon be added which will make the capacity of the mill 30 tons. Mr. Macnevin, of the Washington mine, has returned

from San Francisco. His mine is looking splendidly, I learn from McCullum, the foreman of the mine. There is a large force of men at work in the mine now.

EL DORADO.

VOLCANOVILLE.—Cor. Georgetown Gazette, April 7: The new mill on the Josephine mine started up about a week ago. The old steam mill which stood just on top of the hill, overlooking the river, was taken down by the company in the early part of the past winter, and a new one put up down on the side of the hill towards the river, 200 or 300 ft below the old one. I visited it a few days ago, and found it working splendidly. They have only as yet, 10 stamps running, but intend to put up to more in a short time. The mill is run by water power, 32 ft pressure and a Knight's wheel. It is fitted with all the modern improvements, such as self feeders, rock breaker, etc. About 25 inches of water is used to run the 10 stamps. Everything in and about the mill seems to have been done in a good and substantial manner, and reflects credit upon the workmen, Messrs. Rauney, Copp and Goodpasture. A tunnel enters the mine about on a level with the top of the mill, and as the ore is brought out, is dumped into the bin at the rock breaker, in and near the top of the mill; one man tends the rock breaker, and that was about all the work I saw being done about the mill—improved machinery does all the rest. Work in the Cooley mine is progressing satisfactorily. This is the old Grizzly Flat claim; it has been bonded by a San Francisco Co., who are under the superintendency of George Bower, running a bed-rock tunnel; they intend, in about another month, to "chimney up," when good pay is confidently expected. The Spring tunnel claim up at Mt. Gregory, 2 1/2 miles above here, has been fitted up during the past winter with a hydraulic rig; has been running about a month; have not yet made a clean-up. This is also a San Francisco Co. C. F. Lloyd is working in a bed-rock tunnel on Bunker Hill, one mile east of here. D. C. Webster, on his claim on the Grey Eagle trail, has just raised a chute 20 odd feet, and got through into gravel. Your correspondent is still pegging away in his bed rock tunnel—thinks "there's millions in it." So you see, there is considerable prospecting going on around here, and we think some of us, if not all, ought to strike it. We learn that Jordan & Zombro are now in 150 ft on their large tunnel which they are driving to tap their ledge on Slate mountain. They have not much farther to run. The ledge prospects well for a long distance on the surface, and a shaft of nearly 100 ft sunk on the ledge last season, demonstrated beyond doubt that they have a valuable mine of milling ore. Therefore they are driving in a tunnel suitable for working the mine on an extensive scale. Mr. Benjamin and the Grover boys own an adjoining claim on the same ledge, and are in some way interested in the tunnel. This is one of our new mines which will have a mill put upon it before another year.

MONO.

HOMER DISTRICT.—Homer Mining Index, April 7: The Lake Canyon toll road, between the May Lundy mill and tramway, had been nearly cleared for teams, the tramway and mill put in repair and everything was about ready for putting on a large force of miners, when the heavy snow storm of last week came along and to temporarily checked the movement. The May Lundy mine was never in better condition, and never showed larger quantities or richer ore than at present, and it is confidently believed that the bullion output for the current year will be largely in excess of that of any preceding year in the history of this famous mine. A force of men will be put on this morning to reopen the road, and, should the weather continue fine, the mine will be started up full handed in a few days.

GORILLA.—All three of the tunnels in the Gorilla mine are being steadily pushed along the vein, in ore. The lower tunnel, No. 1, is in 480 feet, the header being 112 feet the center of the upraise which connects it with the tunnels 2 and 3. The additional 100 ft will be added to the upper end of the tramway as soon as the snow will permit, when the mine will be in the best possible condition to pour out a large and steady stream of gold.

MONO LAKE HYDRAULIC.—The 5 ft and 2 inches of wet, heavy snow that fell in the hydrographical basin of Mill creek last week will be of incalculable benefit to the Mono Lake Hydraulic M. Co., as it gives assurance of an abundant supply of water for the season. The company can now put on a full force of men, and will doubtless push the work with redoubled vigor.

GREAT SIERRA.—Tioga—Work is still progressing in the crosscut adit of the Great Sierra mine, Tioga district, but as the company appears to have been financially embarrassed for the past five months it is not known whether or not it will be able to procure machinery of sufficient capacity to drive the adit to the Great Sierra or Bevan lode, its objective point, or whether it will complete the wagon road (begun last September) up the western slope of the Sierra—a prerequisite to the transportation of heavy machinery.

NOTES.—Work is steadily progressing on the Mount Gibbs group of mines, south end of Tioga district, but during the week the working force in the mine was reduced from 12 or 14 to 4 men.

James Moore, of Toledo, Ohio, who spent the greater portion of the summer of 1881 in Tioga district

ganization. We would not be at all surprised to hear that the company would produce enough ore to pay expenses from the first month of its operation. The Valley View mine was heretofore called the "Whisky Diggings," and was worked by Geo. D. Roberts and Harpending for gold, in other days.

RICH COPPER ORE.—Weisslein Bros. have, at their banking house, a number of specimens of rich copper ore taken from a claim in the foothills of Placer county south of Bear river. The specimens embrace gray ore, black oxides and chlorides, and an assay by J. J. Ott, of Nevada City, of the average quality shows them to go 56 in pure copper. The claim from which these rich specimens come has been purchased by the Messrs. Weisslein and other parties within a few days.

THE LITTLE BONANZA.—After an interval of several months Nichols & Co., yesterday resumed work on their "Little Bonanza" claim, to the west of town, and expect before long to be taking out more rich specimens. The water is being pumped out of the drifts, and it is intended to work deeper than before. When work was stopped before on account of the wet weather good pay rock was left in the drift. Six men are at work on the claim.

PLACER.
RAISED WAGES.—Cor. Placer Herald: The Hidden Treasure Co. raised the wages of their employees from \$2.50 to \$3 a day. This is the voluntary act of the owners, and it took their men by surprise. These gentlemen well deserve the rich mine they own. May it continue to pan out better than it ever has.

A GOOD RUN.—Placer Herald: Messrs. Peardon & Hawkins brought to town, last Thursday, 200 ounces of gold, the result of a run of 135 tons of ore from their mine, the Morning Star. The ore for this run was taken from three different places in the mine and shows the high average of \$20 per ton. The Peardon & Hawkins brothers have been working this ledge now for several years, and it has paid them well from the start. They have a good mill, steam hoisting works, and a well opened mine, and all has been paid for from the proceeds of the rock.

PLUMAS.
TAYLOR-PLUMAS.—Greenville Bulletin, April 7: The mill has been busy night and day since a start was made, over three weeks ago; most of the ore crushed has been taken from the dump. Mr. Bransford started a shaft to tap the ledge close to the mill, but was compelled to suspend work upon it soon by the storm; drifting eastward from the winze in the tunnel is continued, so that when work in the shaft shall be resumed, and the ledge reached, there will not be any great delay in opening from the shaft to the winze drift. The ledge is opening out in this drift fully up to what had been expected.

WATER PROSPECTS.—Rain set in on Sunday, a week ago; the storm continued all the week with but little cessation, alternating between snow and rain. During one twenty-four hours the water in Round Valley reservoir raised about six feet, the streams pouring in torrents from all sides; this was before any snow had fallen, and when the area to be covered was not so great as it has since become. The water still keeps raising steadily; on the mountains around there is a depth of about two feet of snow, very ample, with the rains we are now certain to get, to give a full supply for the summer. Before this storm set in the outlook was discouraging enough, but now every one feels jubilant, and confident that we will have a prosperous and profitable season, both in mining and farming in the valley.

GREEN MOUNTAIN.—The mills have been kept running steadily during the past two weeks, and been well supplied with ore of a fair quality. A few hours delay was caused last week by a break in the ditch, but this was a trifling matter and would not make any change worth mention in the result of the month's work. The tunnel is advancing rapidly, and will certainly reach the ledge toward the end of the month; this will make a very important change for the better in the condition of the mine. From what is already known of the ledge in the upper levels it may confidently be expected that a very large body of good paying ore will be opened up in the tunnel.

EAST OPHIR.—This is the name applied to the location made at Crescent by C. H. Higbee, and upon which a shaft is in process of being put down; the shaft is now down 85 feet, but work had to be suspended last week soon after the storm set in, owing to a great increase in the flow of water. Before any more work can be done a pump must be put in, for which preparation is already made. At a depth of 55 feet a ledge of good looking ore was on one side of the shaft, no effort was made to test the extension of the ledge, but as soon as the water shall be pumped out a crosscut will be started and the width and quality of the vein fully tested.

EMERALD DISTRICT.—A brief suspension of work was caused last week in the tunnel on the Lucky S. mine, but work is now going on again all right. A heavy stream of water was encountered in the face of the drift a day or two ago, and this with other indications, proves that the ledge will very soon be reached.

INDIAN VALLEY MINE.—At the Indian Valley mine, the use of steam was discontinued this week except for hoisting. This mine is the only one in the district provided with steam power so that when the supply of water fails the engines can be started up and work continued as usual, both in mine and mill.

GREEN LEDGE.—The arastra at this mine was started two weeks ago last Monday; at the end of the first week a clean up was made, and an amount of gold obtained that would seem to warrant the building of a mill.

GENESSEE MINE.—The Genessee mill was started up for the season two weeks ago last Monday, and has since been running steadily, day and night, on good rock.

SAN BERNARDINO.

BORAX MARSHES.—Calico Print: Besides the large borax fields owned by the Seares Bros. and W. T. Coleman & Co., in Death Valley, there are also other localities in this county that have been taken up by other parties. About eight miles southeast of Hawley's station, at Coyote Holes, there is a marsh of two or three hundred acres, surrounded with an immense deposit of borax. The marsh is chiefly a large deposit of carbonate of soda. The borax is almost pure, of a fine quality and known as cotton-ball borax. It is necessary, in order to reduce it to a crystallized form, to mix with it fifteen

per cent. of carbonate of soda, which nature has, it seems, placed there for that purpose. The best part of this marsh has been located by Wm. Curry, E. J. Miller and O. H. Baker. The property has been bonded by the James brothers for \$12,000. Borax is worth thirteen cents a pound in San Francisco, and it is not very expensive to reduce the borax, so that the parties interested are likely to make some money out of the enterprise. Daggett station is the nearest shipping point, which, fortunately, is not as far from this borax deposit as it is from others.

SHASTA.
WHISKYTOWN.—Cor. Shasta Courier, April 7: In our last issue, Kesler & Andrew were represented as having sold their mine for \$1,000, when in reality they have bonded it to San Francisco parties for \$4,000 for 60 days, \$1,000 being paid as a forfeit. J. D. Blair, A. Saulan, W. Andrews and W. E. Hopping have bonded their mine to the same parties for \$4,000. I. W. Zent has been engaged as superintendent and will soon put a force of men at work. The grand old rain has caused a jubilee among the miners; Kesler & Andrew have started their arastra once more and the Mad Ox mill has again resumed operations, where, according to Mother Rumor, a large force of the moon-eyed Chinamen will be employed, to already being at work there. The placer miners are making the dirt fly. The locating of quartz claim epidemic has broken out here, and the fever runs high, also all of the male portion of the community having it in its most malignant form.

SIERRA.
KEYSTONE.—Mt. Messenger: Geo. Jordan has been working several men at the Keystone during the winter. He will make a run of the mill as soon as he gets water. The Ruby Co. are getting good pay at the South end of their works. All the mines at Eureka now have a good head of water, and are in full blast.

TRINITY.
RUNNING WATER.—Trinity Journal, April 7: After many days of waiting and a number of days spent in cleaning out the main ditch, Mr. John Yule tells us that he commenced active operations in the Bolt Hill claim on Saturday last. He now has strong hopes of a fair Spring and Summer run and believes that if such is the case the mine will make a splendid showing. At the McGillivray property, the hydraulic elevator is in full blast and doing good work. Mr. Yule thinks that between running gravel down hill in one mine and running up hill in the other he ought to make a glorious success.

TULUMNE.
THE MINING BOOM.—Mountain Democrat: A pioneer and prominent resident of Mud Springs township writes as follows, under date of April 3: "The chief mining boom of this season will certainly be in the vicinity of Mud Springs. Recent developments prove the Greenstone lode to be one of the curiosities of the time. It is extremely rich in gold, and is known to extend for miles. It is a fissure vein on the west side of the tale, with granite for a foot-wall. Several companies have sunk upon it from 10 to 100 feet, and all of them have found deposits that paid from \$10 to \$200 to the pan of free gold, besides from two to four feet of good milling ore, and the deeper they go the better it gets. The pay appears to be uniform; in fact, it is a continuous vein of gold through the center of the great gold-bearing belt of the State. As for quartz, we believe and know we have some of the best in the State. The celebrated Amador or Hayward lode passes right through here, in its virgin condition, awaiting capital for its development. The 'Davidson mine' upon said belt has been tied up for over 30 years, in the hands of men without means to work and develop it, but Peter Gross, the indefatigable and successful prospector, has succeeded in bonding it, and is rapidly completing a ten-stamp mill, with which he will soon test its value. He is highly elated with the formation and prospects, and claims that he will have one of the most permanent and best paying mines in the State. There are eight or ten other claims on the same lode in this vicinity, all of which prospect well in free gold, upon which capital would be expended, mills built, and work actively prospected, if Gross' venture should prove successful.

RAPPAHANNOCK.—Union-Democrat, April 7: Work on the Rappahannock mine, near Rawhide, is progressing finely. A new boiler has been added to the works. The shaft is down 190 feet in ore that looks well. This week it was expected to commence crosscutting with every prospect of getting rich ore. Richard Chute recently bought into the mine which has been incorporated. This work of development will be pushed with the promise of profitable results. The same owners will also commence work immediately on the O. K. mine, situated on the same vein below the Rappahannock.

THE LAMPHEAR MINE. a northern extension of the Confidence, was sold this week to Richard Chute and J. A. Davis. The purchasers made arrangements immediately for putting in hoisting works and fully opening the mine. A rich chute of ore shows from the surface, down to the depth of 30 feet, deep as it has been opened, running 60 feet on the vein. Assays made from different parts of the vein go to a high figure. A quantity was tested by the milling process and yielded \$43 per ton. This is believed to be the chute that was hunted for in the Confidence mine. On the 800 level of that mine a drift was run a long distance to find it, but the search was stopped by water, which came in such quantities it could not be handled. More than a million dollars was taken out in the Confidence from the same character of ore. There is every reason for believing the Lamphear will prove to be similar to its predecessor in richness. That the gold is there, miners have no doubt, and the energetic parties that now have taken hold of it will leave nothing undone to get it, thereby enriching themselves and benefiting the community at large.

OAKLAND MINE.—Tuolumne Independent, April 7: This mine is situated about three and a half miles east of Columbia, Tuolumne county, in the richest mineral belt traversing the State, being adjacent to the celebrated Arnold mine, Read mine, Page mine, and other valuable mines. The ledge was discovered something less than a year ago, by Merritt Ham, one of Tuolumne's pioneer prospectors, and shortly after purchased by an Oakland company. This Co. have rapidly pushed the work toward developing the mine since coming in possession of it—having run a level on the lode 300 feet, and sunk a shaft 160 feet. A large percentage of the vein matter produces high grade ores, the gold seeming to be quite evenly disseminated through it. A new mill has been placed on the mine for the reduction of ore, and is

now in readiness for operation. Instead of a stamp mill the company, in order to economize, in a measure, in expenditures that necessarily occur in making a fair test to determine the value of ores through the ordinary milling process, have in place the Tustin Pulverizer, the first mill of the description introduced into the county. The inventor claims this pulverizer to be equal in working capacity to an ordinary five-stamp battery, and less than one half the cost of stamps. We shall look forward to the working results of the Tustin Pulverizer with the greatest interest. The company have in place, also, in connection with the pulverizer spoken of, Huntington's Improved Separator and Concentrator, combined, which machine seems to produce every result claimed for it by the patentee. The writer witnessed this machine in operation Thursday last, and, judging from its modus operandi, is as near perfect as machines of this description, aiming at one and the same purpose, is likely to reach for some years to come.

Nevada.

ARABIA DISTRICT.

SHIPPING ORE FROM OREANA. H. G. Wingate informs us that George Lovelock is shipping ore from one of his mines in Arabia district, east. The ores of Arabia are principally argentiferous galena, some of which contain a high percentage of lead, and from \$60 to \$150 per ton in silver. Two earloads of the ore is now being shipped east, and if it pays it is said a earload a day will be shipped.

CORTEZ DISTRICT.

BULLION.—Silver State, April 4: Yesterday, Wells, Fargo & Co.'s Express took west 16 bars of bullion, of the assayed value of \$24,615.82, from S. Wenban's mine in Cortez district. The mine which produced this bullion, and the district in which it is located, is the oldest in eastern Nevada. The machinery for the mill was hauled over the mountains and up the Humboldt in 1865, when the Indians were on the war-path. Cortez is situated southeast of Beowawe, in Eureka county, about 25 miles from the railroad, and it is said that Chinese labor is exclusively employed by Wenban.

RELIEF DISTRICT.

DEVELOPING.—Silver State, April 4: Edwin Darrow, who is engaged in mining in Relief district, on the east side of the Humboldt range, was in town yesterday. He represents the Batavia & Pacific M. Co., and is engaged in developing what was known as the Relief mine, which the company purchased some years ago. He is engaged in running a tunnel, which is now in about 300 feet, to the lead. Some years ago this mine produced some \$60,000, and carried exceedingly rich ore, some of which was shipped to Swansea, in Wales.

Arizona.

PRESCOTT NOTES.—Courier, April 7: J. M. Roberts is our authority for stating that the Copper Mountain mine is a big fellow. A town is growing up around it. T. J. Eaman has given the Courier permission to say that the Black Warrior mine will soon be giving employment to a great many men. The Franklin mine, in Turkey Creek district, is opened by shaft and tunnel. Ledge looking well and yielding a great deal of rich rock. C. D. Brown has gone to fix mining machinery in Turkey Creek district. J. A. Robinson says the Belle mine is yielding lots of ore. Gov. Tride thinks well of the Lynx creek hydraulic diggings. It is reported that the Howell Reduction Co. will soon have two more smelting furnaces. The tunnel in the Franklin mine, Turkey Creek district, is in a distance of 202 feet. The ore is said to be good. Openings are being made above and below this level. Dr. Farnham, superintendent of a small mill and some mines, in Walker district, came to town yesterday. His mill is the common stamp mill. It has been running upon ore from the Wadleigh. The recent call for an assessment on Tip Top stock has had the effect of making a few timid holders of the stock give credence to the report that the mine had petered. We learn from Messrs. Al. Whitney and Jake Marks, who have recently returned from the mine, that it has some \$75,000 worth of ore in sight and is looking as well as at any period of its existence. The depth attained by the present workings necessitates, however, the erection of better hoisting machinery, and it is to secure this machinery that the present assessment is levied. The Clip mill, of Silver district, drops his stamps for the first time in its history to-day. This mill and the Clip mine, which is run in connection with it, are owned principally by Messrs. Bowers, Shipman and Hubbard, and from reports received of its richness and extent it promises to be one of the leading mining properties of the Territory. So far as good management may tend toward the accomplishment of this result the property could not be in better hands than those of the gentlemen named. Mining experts speak in high praise of Henry Wickenburg's Iconoclast mine. It is a matter of regret that so good a property should not, however, be worked to the extent its merits require, the present holders lacking the requisite means to develop it quickly.

GOLDEN RULE GROUP.—Tombstone Republican, April 7: Notwithstanding the frequent outbreaks of hostile savages and other causes which have conspired to retard the progress of this section of Arizona, the well known richness of our mineral resources is having its legitimate effect; and despite the drawbacks referred to, Cochise county is slowly but surely taking rank as the most desirable place known for the investment of capital in mining enterprises. The Golden Rule group of mines are located two miles east of Dragoon Summit. They have been opened by various cuts and shafts, the deepest workings being only 175 feet in depth. The ore bodies thus far uncovered are said to be of vast extent, while it is claimed by those well informed in regard to the properties, that careful assays give an average return of \$60 per ton in gold. A syndicate of Silver City, N. M., capitalists have secured control of the Golden Rule mines, and from the manner in which they have commenced operations, it is probable that before the summer is past, regular shipments of gold bullion will be made. A 20-stamp mill has been ordered, and will be on the ground about the 10th proximo, grading for the mill site having already begun. The promoters of the enterprise confidently expect to have the mill running by August 10th. Water will be obtained from springs in the Dragons, seven miles distant, a substantial pipe-line furnishing

the necessary conduit to the mill. C. P. Crawford, the well-known banker and capitalist of Silver City, is president of the company, and Henry Booth secretary. The resident agent at the mines is Samuel H. Eckles, whose name will inspire confidence in the success of the undertaking. The stock is all held by residents of Silver City, with the exception of a small amount held by W. A. Farish, and none of it is for sale. It is the intention of the company to work the mines legitimately, and not as a stock-jobbing scheme. Those principally interested are practical mining men of many years experience, and they are serenely confident of the extent and richness of the properties over which they have secured control.

DELPHINE.—Final Drill, April 7: Mr. Deutch is working the Delphine mine, near the Surprise. The shaft is down about 80 feet, the drift from the bottom of the shaft is about 60 feet and the ledge will soon be reached. The ground is easily worked. But little blasting is required.

The machinery of the Queen Creek smelter has been overhauled and is now in complete working order. They are sinking for water, close to the creek. They are down 24 feet in a layer of clay and are now curbing. After that, the sinking will continue till the clay has been cut through, and a large body of water is expected. A considerable supply of ore is on the ground and they are hauling ore daily. They are waiting for coal and coke.

New Mexico.

MINING NOTES.—Southwest Sentinel, April 7: Nearly every pan of sand taken from the bed of the Rio Grande river shows at least one color of gold. A rich strike is reported to have been made in the Coyote district, Lincoln county, which is said to assay as high as \$1,600 is gold. The 10-stamp mill on the Occidental, in the Black Range, is pounding away and the results are all that was anticipated. The La Plata mines, next to the Hard Scabble, in the Magdalena mountains, is located on the same vein, but appears to be richer in lead ores, though this feature may disappear with depth. The Black Knife mine, in the Black Range, is now being worked by Illinois capitalists, under the superintendency of Col. Noulton. The lode is worked to a depth of 123 feet. The vein matter below the 100 level greatly improved, and a 10-ton smelter has been erected on the Cuchillo Negra creek, two and a half miles distant from the mine, and a good wagon road graded from the mine to the mill.

Montana.

THE POSER.—Inter-Mountain, April 3: The lessees of the Poser, Dennis Leary & Co., are meeting with splendid success in the development of the property. From the bottom of the shaft, which is 80 feet deep, a drift is being run on the ore shoot and a breast of ore 10 feet wide is being extracted. With a force of only five men, the product is made to average 15 tons a day. It is being shipped to the Silver Bow mill where it pulps from 32 to 38 ounces. The Poser shows one of the most extensive ore bodies in the camp, and the fact that there is scarcely a wagon load of waste on the dump is evidence of its uniform milling quality.

The indications point to a big output for the Alice company this month. The mills are in fine running order, and the Magna Charta never looked better. The 100 level of the Alice is also good for 25 tons a day, and barring accident \$100,000 is what the Inter Mountain estimates the product of the company for April will be.

Utah.

STAR DISTRICT.—Salt Lake Tribune, April 5: From persons in from the south we learn that in the Star district, which lies 12 miles southwest of Frisco, the prospect is bright in mining matters. The Kanarrab mine, owned by Sloan & Kemple, has reached a depth of 230 feet and is in galena ore three feet wide, which assays about 50 ounces silver, and from 60 to 70 per cent. lead. They have a slope extending upward 128 feet. The ore being extracted is sent to the Frisco smelter. The Stalwart, owned by W. S. and P. S. Martin, has reached a depth of 210 feet, at which point the vein is about 12 inches wide, the ore being argentiferous and horn silver with a quartz gangue. As depth is gained the quality of the ore improves. Eight years ago the owners sunk a shaft to a depth of 60 feet, and dug out all the ore to be found. It looked as if the property was worthless, but the owners showed their faith in it by going 50 feet north and sinking a new shaft. The first 75 feet, the thin vein of ore averaged 200 ounces silver, below which point it has been getting better and now assays 520 ounces silver, \$10 in gold and about 35 per cent. lead, and the vein is unbroken. Some of the other claims in that locality give fair promise, and persons interested in the Star district feel buoyant over the outlook.

A REVIEW.—Salt Lake Tribune, April 8: The output of the Horn Silver for the week was 24 cars of bullion, of the value of \$72,000. Previous shipments for the present year, \$886,500; present aggregate, \$958,500. We here no more of the cave hindering present work and the plentiful extraction of ore. The rich strike newly reported is in a portion of the mine not affected by the giving away, and at any rate the huge product of the mine is undiminished by the mishap. The Ontario shipped for the week, 44 bars of silver, valued at \$44,585.71. All is going well, the dead work progressing in good shape, and the ore bodies being entirely satisfactory. Undoubtedly, dividends must be resumed very soon. The Crescent Co. is reported to have made arrangements for large shipments of ore to this city, which will begin as soon as the roads get in passable condition. The Mammoth is not in the satisfactory condition that was to be wished. When work stopped by reason of the lapse of pay-day, the laborers held possession of sundry of the property of the company as security for their wages; but they subsequently released all this and went to work. But the manager, who was expected shortly with funds to square accounts, has not yet returned. Full confidence, however, is felt that the outcome will be well, for the progress of the work has developed not only the sufficient richness of the immense bodies of ore in the mine, but the entire practicability and paying character of the matting operations. The Frisco Co. shows shipments this week of one car of bullion, of the value of \$2,009.14. In all directions, the mining outlook was never more promising than it is the present season.

Prospecting for Gold and Silver.

The following is from the Salt Lake *Tribune*: For the thirty-fourth Spring in the camps of the Pacific Coast the prospectors are fitting out for the discovery and occupation of new ground. At first the limit was Nevada, Sierra, Plumas, Butte, and Placer counties in California. With another year Siskiyou was reached, and all the long line of hills from Mount Shasta to Mariposa. It was then so many colors to the pan, so many dollars or ounces to the day with rockers. After awhile the long tom was invented and it was confidently told that with it a miner could double his work. Later a year or two the first great deal began in Mariposa, and still later an English company built a costly but crude quartz mill above Marysville, at Brown Valley. Sir Henry Huntley was in charge, and though he knew very little about quartz or how to save gold from it, he rode a magnificent blood horse and looked as though he might be familiar with all the chemistry of the rocks. Those were the days of wild spears, of fandangoes, of pack trains, and when in some little building a theatrical play was advertised, and when on the little 12x14 stage a girl in spangles appeared to sing or to execute a fancy dance great hearty shouts greeted her and the stage was showered with gold pieces. Those were the days of generous hearts and quick, sharp quarrels. The fashion of honoring murderers and hanging horse thieves was inaugurated then on this coast. With every year new mines were found and new improvements in working them were made. Those were the days when rivers were turned aside at great cost, and when, not unfrequently, just as the day for commencing to reap a reward corresponding with the outlay arrived, the rains came and all the labor and money expended were hopelessly lost.

In Calaveras, Amador, Nevada, Sierra and Plumas counties, quartz mining and milling grew to be a business, but it was uncertain; it was something which men knew nothing of, but the thought that if from the ore the precious metal could be obtained, it meant quick fortunes, such as Astor and Girard gathered through long years of toil, stimulated men to keep trying. Who ever thinks of Astor and Girard as rich men now? Those were the days of steamers, those were the days when letters from home were kissed and cried over as never letters were before. Then hydraulic mining was invented, and the hills with their shaggy pines began to bow before the new destroyer. Every Autumn the immigrants came in from the plains with the crowd, and as the settlements in the deep hills grew permanent, toll roads were introduced and stages and big teams; year after year the volume of gold with increasing millions rose and floated away to the East and became an infusion of new blood to the arteries of trade.

Those were the days of clipper ships, and every time a man went down to San Francisco from the hills, his story on his return never failed to include descriptions of some new ship which had come into port and which was more beautiful than any ship had been before. And gradually at the point of the Peninsula the sand hills melted away and a regal city took form inside the Golden Gate. But the placers began to fail; the beards of the early miners began to grow grizzled, and they commenced to grow garrulous when they talked of the winter of '49 and the spring of '50. A few of them tried farming, and when the river bottoms were tested the result was astounding. There was better wheat and more to the acre than the richest lands of the East could produce. Still, as yet, all the upper lands of the valley were flower crowned, and old miners did not take kindly to farming. Something new was wanted. So in 1857, when it was told that in British Columbia there were rich placers a new exodus began. The steamship companies fanned the flame and the exodus grew to be a stampede. It was short-lived, but it was fatal to many a trader of easy fortune; fatal to the future of many a miner, for thousands in that journey and search acquired the restlessness which never more permitted any contentment in this world. At last from beyond the Sierras a man carried some peculiar looking material to Placerville and was told there by Prof. Frank Stewart that it was black subphosphates of silver, and he advised the man to have it assayed when he reached Sacramento. The result was a return of \$1,400 to the ton. Then there was a new excitement indeed. Then the energy of the California mountains was transferred to the other side; then farms and gardens were left to camp followers; then the exploration of the desert began, and what has happened since is modern history. How the boys learned to timber them; how Idaho, Montana, Arizona and Utah were explored; how at length the locomotive came along, is it not all written in the chronicles of these days? But the prospector still haunts the hills; with every year he fixes his pack and blankets and starts for new fields with the old dream in his heart and the old eager look in his eyes. This year he means to bring up in the Kootenay country and he goes away with the determination that if he fails this year he will try Alaska next. His generation is almost gone, and his work is almost finished.

WOOD PRESERVATION.—M. Favol, a French investigator, has found that the cresote treatment for the preservation of wood sometimes doubles the durability of oak timbers used in collieries, but has little influence on pine. He further says that oak prepared with ferrous sulphate lasts ten times longer than in its natural state. It should be immersed 24 hours in a solution of 200 grammes of ferrous sulphate.

Is Cottonwood Timber?

The Government Land Office has decided that the cottonwood is a timber tree, and that it may be used in planting land which the settler wishes to acquire under the timber culture acts, and yet there are claimants who desire to acquire land with cottonwoods already growing on it under the timber culture acts. The Commissioner of the General Land Office has lately issued a decision in this matter, in which he says: Under the current rulings of this office, and the Department, the cottonwood is regarded as a timber tree, and cultivation of the same by timber culture claimants is accepted as a compliance with the law, so far as the quality of the timber is concerned. While it is shown by the testimony that this tree is not used to any great extent in the locality for manufacturing purposes, building, fencing or firewood, yet it appears that it is used for out-buildings, houses, fences and firewood occasionally, according to the notion or necessity of the settler, or the distance from timber of a superior

MONO COUNTY.—During several years residence in Mono county, and by extensive exploration and close observation, we have gathered a vast amount of interesting information relative to the early history, the geography, topography, geology, mineralogy, hydrography, scenography flora and fauna of that interesting and rugged portion of the high Sierra embraced within western Mono, northeastern Tuolumne and northern Mariposa, from Bodie to Yosemite and from Owens river to the confluence of the three main branches of the Tuolumne river—including the auriferous gravel range of Mono, the mining district of Jordan, Homer, Tioga, Prescott and Mount Hoffman; Mono Lake, its islands and coralline and volcanic surroundings; the principal mountain peaks in this portion of the chain, as Dana, Lyell (and its residual glacier), Castle Peak, Warren Discovery, Theller, Comess, Bill Williams, Gilcrest, the Minarets, Cathedral, Hoffmann, Cloud's Rest, and the domes about Yosemite and northward; the thermal, solfataric and other mineral springs; the great glacial gorges on both slopes, and other evidences of

THE ORANGE KATYDID AND ITS FOE.

kind. The cottonwood tree, as it grows in the locality, is, therefore, not either useless for the purposes mentioned, or merely ornamental. This is apparent from the evidence in the case. The entry is held for cancellation, for the reason that the land was not subject to timber culture entry, the same not being prairie land or other land devoid of timber.

LEAD POISONING.—The *Pioche Record* says: "Bullionville is undoubtedly the unhealthiest town in the State, as the many poor victims of lead poisoning can testify. It is an exceptionally dangerous abode for children, as they stand no show for recovery after the poison from tailings becomes permeated through their system, as was the case with two little ones that succumbed during the past few weeks." More arant nonsense than the above has never been put in print. The idea of one place being more unhealthy than another, as regards lead poisoning, is about the same as to say that poisoning by strychnine is more dangerous and deadly in one town than in another. Such English as: "After the poison from the tailings becomes permeated through their system," is enough to kill all the children and the majority of the adults, not only in the town of Bullionville, but for fifty miles around the place.

The Orange Katydid.

In his report on the orange insects of Florida and California, Prof. J. Henry Comstock introduces the drawing which we reproduce on this page. The insect is the "angular winged katydid"—*Microcentrum retinervis*. Katydid is generally harmless insects; but there is perhaps no insect of large size which is so destructive to the foliage of the orange tree as is the species named.

In describing the insect, we begin with the eggs, as shown in the engraving. Fig. 1 shows the female depositing her eggs. Prof. Comstock, in his report, remarks that the eggs (Fig. 1 a), were found to be laid in two ways. The first, as detailed by Prof. Riley, in a double row down a twig, which had previously been chewed with the jaws and otherwise prepared for a place of deposit. The eggs of each row were laid alternately, and those in the same row were deposited in such a manner that they overlapped, the first egg having been placed in a sloping position, and the end of the second forced down under the raised end of the first. Upon twigs this was always found to be the arrangement, but upon the leaves it was different. In the first place, there was but one row. This row was laid along the edge of the leaf, each egg obliquely towards the tip of the leaf, with its anterior end projecting beyond the edge, and its posterior border slightly overlapped by the preceding egg. The edge of the leaf was in no way roughened for the reception of the eggs, which were usually deposited upon the under surface. The shape of the eggs was a long oval, somewhat straighter upon one long edge than the other, and nearly flat, thickening somewhat as the hatching time approached.

With the leaf-laid eggs, the young katydid, in every case, issued from the end of the egg which projected beyond the edge of the leaf, and the empty eggs, with their split sides, were readily distinguishable from the sound ones, the difference appearing similar to that between a closed oyster shell and one partially open. The split is not confined to the external end, but also extends down the outside edges, which, by the way, is always the straight edge. With the double rows of eggs upon twigs, the straight edges of the two rows approximate, and it was from the upper end and inner border that the larva made its exit.

From eggs collected in Florida in February the katydids commence to hatch, and almost immediately began to eat, feeding at first only upon the surface of the leaves (Fig. 1b.) In about nineteen days they shed their first skins and ate them up before proceeding with their leaf diet. There were three molts in addition to this first one, the third giving them large wing pads, and the fourth making them perfect winged insects. The cast-off skins were eaten after each molt, and in one instance one of the katydids was killed and partly devoured by his companions while yet in the soft and helpless condition succeeding a molt. The quantity of leaves eaten by these creatures during their active period of growth was something enormous, and afforded a good index to the amount of damage which must be done where they occur in any number.

Fortunately for orange growers there is a chalcid parasite upon the egg of this insect, which seems to be quite common in Florida, at least. It may be known as the *katydid egg parasite*, as no other has been found, and as it is not known to infest other insects. The adult insect is a curious looking individual; the female (Fig. 2, the male Fig. 2a). It is about 13 to 14 of an inch in length, with dusky wings and with an abdomen which it can elevate over its thorax in a strange way. The eggs of this parasite are deposited within the eggs of the katydid, and its larvae hatch and undergo their transformations within the eggs of the latter, issuing at last as adult flies through circular holes (Fig. 2b) which they cut through the shell. There is never more than one adult parasite to issue from each egg, for although more than one parasitic egg may have been originally deposited in the egg of the host, only one arrives at maturity.

No better remedy for the injuries of this insect occurs to us than the collecting of the large and conspicuous eggs during winter. When collected, however, they should not be destroyed, but placed in a box covered with a wire gauze until spring, in order to allow the parasites to escape.

DESERT LANDS.—The Secretary of the Interior has decided that in the case of lands claimed under the desert land law, that the question of character of lands that have been reclaimed from a desert state, and are now producing crops by means of irrigating ditches, etc., are not subject to entry under the desert land laws. A desert land entry of 640 acres cannot embrace land in such form that the tracts in linear extent shall exceed one mile and a quarter. In entries of smaller quantities, the side lines must be reduced in proportion. A school section or part thereof cannot be embraced in a desert land entry.

A THROAT ELECTRIC LAMP.—At the last meeting of the Leeds and West Riding Medical-Chirurgical Society, Mr. Margetson, of Dewsbury, exhibited an incandescent lamp, designed by himself, and used by him since October last in examining the mouth and throat. The globe was about the size of a walnut. It can be held in the mouth for two minutes without discomfort from the heat.

THE STRASBURG CLOCK AND PLANETARIUM.

The late transit of Venus curiously proved the accurate calculations of the ancient makers of that famous horological curiosity, the Strasburg clock. A few days before the transit, the *American Register* tells us, visitors to the cathedral inspecting in the planetarium attached to the clock, noticed that one of the small gilt balls representing Venus was gradually moving toward a point between the sun and the earth, and on the day of the passage the ball stood exactly between them. Old Conrad Dasypodius, the Strasburg mathematician, superintended the manufacture of the clock and its accompanying planetarium some time between 1571-4, the dates differing according to various authorities; and it is interesting to note that after 300 years of existence the clock faithfully fulfils the calculations of its dead inventor.

Homer, Jordan, Tioga and Prescott Districts.

This (Homer) district is just now attracting a great deal more attention in the east than many of our own people are aware of. Capitalists there have ascertained in their own chosen way and time that the mines here rank with the richest gold quartz mines in the world, and the long continued improvement in depth of the May Lundy and Gorilla has definitely settled the question of permanency. These facts, coupled with the visits of mineralogical and crystallographic experts, indicates an active interest among eastern capitalists in the mines of this district, and we are assured that some heavy sales may be expected at an early day, to be followed by a period of active development work by companies possessing ample means. This is all Homer district requires to make it one of the heaviest billion producers on the coast.

In Jordan District, adjoining us on the east, the hydraulic mines have been put in good condition and active operations begun, though the water supply is still somewhat limited, owing to the frozen condition of the small tributary streams in the high Sierra. The Detroit Copper Company has for some time been engaged in straightening up its affairs and getting ready for active operations both in the mine and at the furnace. Some good developments have been made in heretofore unknown claims in Jordan District during the winter.

In Tioga District, adjoining Homer on the southwest, work progressed all winter, both in the Great Sierra tunnel near the north end of the district and on the Ella Bloss and Golden Crown group at the south end; though we are not advised as to the progress made or prospects encountered, further than that the Ella Bloss shows a large ledge of high grade silver ore.

Prescott District, next south of Tioga, and, like the latter, covering the summit and eastern slope of the Sierra, though containing many large lodes of fair grade gold and silver (milling and smelting) ore, is still lying idle, except when the silence is broken by the annual labor required by law. And yet Prescott will doubtless, in time, show up nearly as many and quite as productive mines as either Tioga or Homer. The base or carbonate belt of Prescott traverses the westerly portion of the district, in a southerly direction, from the head of Parker canyon, under the residual glacier of Mount Lyell, to the head of the North Fork of Rush creek, while the free ore belt (silver) crosses, with the same general trend, the easterly brow of the great eastern promontory of the same lofty mountain. During the winter, a group of mines on the carbonate belt, near the head of Parker Canyon, was sold to some California capitalists, who, it is understood, intend opening the mines and putting up a furnace as early this Spring as possible. Negotiations have also been going on for some time (with fair prospects of success) for the sale of a group of the best prospects of the eastern or free belt to an English syndicate, and altogether, it looks as though there was a "boom" in store for Prescott also, in the near future.

Below will be found some details of mining operations hereabouts:

Gorilla.

This mine is now in excellent condition for the advantageous employment of a large force of men during the present season, and must add greatly to the gold billion yield of this district during the year and thereafter. During the winter connection has been made between tunnel No. 1 and tunnel No. 2, 400 feet above, and as tunnels 2 and 3 had previously been connected by a 70-foot upraise, the mine is thoroughly well ventilated. Tunnel No. 1 runs in and along the ledge 475 feet, while at a point 350 above and 50 feet below No. 2, drifts have been run in the ledge both ways from the upraise—70 feet one way and 30 feet the other—both in fine ore. The vein varies from three to four feet in width, while the pay ore maintains a very uniform width of two feet throughout the various workings. A substantial three-rail tramway has been constructed from Wasson Valley 3,200 feet up the mountain side, leaving only 300 feet yet to be built to connect the lower tunnel with a good wagon road leading down one mile to the company's reduction works, which will next week be put in thorough repair for the reception and reduction of ore.

Mono Lake Hydraulic.

Work was resumed by the Mono Lake Hydraulic Mining Company some two weeks since, under the direction of Supt. Francisco Butler. Up to the present time there has been a scarcity of water, owing to the ice bound condition of the tributaries of Mill creek, but the flumes and sluices have been put in first-class order, and the big cut through the great gravel bed, extending from Mono lake up to the mouth of Mill creek canyon is being extended and got into such shape that it is believed the mine can be made to pay handsome dividends as soon as the higher mountains begin to yield up their winter storage of water.

HAIR BELTING.—In Germany, hair belting has been coming into use for some time, and is being quite generally adopted. It is said to give a rougher surface, with a surer clutch, and can be used of less breadth than either leather or rubber.

USEFUL INFORMATION.

How to Test Machine Oils

The *Druggist's Circular*, after alluding to the wretched quality of most of the "machine oils" in use, gives the following simple method of testing the value of such oils for lubricating purposes:

A good plan to test a lubricating oil is to take several kinds of the same article, one of which, being well known, may serve as a standard, and to place single drops of each in a line across the end of a piece of plate glass about twenty-four inches long, one end being six or eight inches higher than the other, to form an inclined plane. The drops of oil run down this smooth plane in a race with each other. The quality of the oils for lubricating purposes is shown by the distances traveled and the trace left by the drops. Thus, on the first day sperm oil will be found in the rear; but it will in time overtake the rest and retain its power of motion after most other oils have dried up. A light-bodied oil flows quickly, like water, but also dries quickly, whereas, what is needed is a good body combined with a limpid flow. Many oils have a good body, but have a tendency to gum; and this will be distinctly shown upon the glass. It is scarcely necessary to remark that the test slip should be covered from dust while the experiment is being made.

The above method will show the physical qualities of different descriptions of oil; but if the presence of acid is to be detected, another simple device may be adopted. In a sheet of bright copper a number of shallow pits are made by the blow of a round faced hammer. Samples of oil left some days in three dishes on a shelf in a warm room will show, by the formation of verdigris, where acid is present. The existence of a blue tinge of fluorescence in a glass phial of oil is frequently assumed to indicate the presence of mineral oil; but this is an illusory test since the same effect is frequently observed in the purest and freshest vegetable oils.

Be Careful.

A complete record of the number of persons who lose their lives, or are terribly maimed, by woodworking machinery in the United States every year would be a ghastly one. Almost every day the daily press tells of one or more accidents of this kind, and when the immense number of daily papers, each recording only such as occur in local establishments, is taken into consideration, the spectacle is an awful one to contemplate.

Whether or not all of these so-called accidents may justly be called accidents in truth, may be questioned. If a workman loses a hand or finger by sheer carelessness, he is hardly entitled to the privilege of calling his misfortune an accident. Indeed, it has been held by profound thinkers that there can be no such thing as an accident. Machinery builders may claim that with their machines it is next to impossible for the operator to be injured, but the truth of the matter is that no machine was ever designed, nor ever will be, that will not quickly resent any undue familiarity with it while in motion. Probably the majority of machine operators are injured by allowing themselves to become careless. Having run the machine a year or two, all thoughts of danger in connection with it are banished from the operator's mind, and in an unguarded moment he loses a limb or his life by the machine he thought he knew so well. Wood-cutting machinery must of necessity be driven at such high velocities, that nothing short of eternal vigilance will ensure safety, and even this can not be relied on. No man should ever trust a machine. If it gets him in its power, neither entreaties nor tears can save him. It has no pity, no remorse. It will chew up a new man every day in the week, and still hum away busily and contentedly, waiting for more. No person who runs power machinery is safe. The best he can do is to keep his eyes and ears open, his brain clear, and his thoughts strictly on his business. Be careful!

WHAT IS SOAP?—Soap consists of an alkali in combination with a fatty acid. The alkalies principally used in soap manufacture are soda, potash and ammonia. The acids are chiefly oleic, stearic, palmitic and margaric. Soda forms the hard soap, potash the sweet or soft soap, and ammonia the kind of soap used in medicine, technically called liniment. Soda soaps will vary in hardness according to the acid employed. Stearic and margaric acid yield harder soaps than the oleic and palmitic. Soap, although it is of so much importance, is not a very reliable compound. Soap may, by dexterous management, be made to contain eighty per cent. of water, and twenty per cent. may be considered a minimum, and forty per cent. an average amount, it is no wonder that various results are obtained from apparently the same material. Various samples of commercial soap are found to contain the following substances: Glycerine, silicate, sulphate, chloride and carbonate of soda, rosin, gelatine, Fuller's earth, Cornish clay, ground flints, potter's slip, farina, dextrine and other substances.

VENEERING is said to have originated with the art of cabinetmaking, and was used by the Egyptians 2,300 years ago.

A BULLET-PROOF CURTAIN.—Experiments lately made at Liepsie with a cuirass made of steel, the formula of which is not stated, indicate that the new material combines both tenacity and durability in the highest degree. The steel plate of the cuirass in this case was only .06-inch thick, and lined inside with a layer of wood; and eleven rounds from a Martini breech-loading rifle, fired at a distance of 175 yards, only two of the bullets pierced the metal, and even these were completely flattened and stuck in the lining.

BEATEN ALUMINUM LEAF may now be obtained in books, like silver leaf, and is largely used instead of silver for decorative purposes. Mr. Levison suggests heavy aluminum leaf as a substitute for tinfoil for coating Leyden jars, and similar electrical apparatus. Area for area, it does not cost much more, is much lighter, and permanently retains its polish. A book of fifty leaves of aluminum, of the ordinary thickness, costs twenty-five cents; of a thickness suitable for Leyden jars, fifty leaves, about four inches square, costs one dollar.

TO RENDER WOOD NON-INFLAMMABLE.—A recent test of a new method of rendering wood non-inflammable, was made in New York city. The preparation is a chemical one, the ingredients not being made public. Georgia pine charged with it and subjected for thirty minutes to a heat of 2,000 degrees, was only slightly charred. One of the inventors claims the chemical will protect the wood a number of years.

A NEW GROCER'S SCOOP.—The Boston Lamina Wood Co., Boston, Mass., are making tea and grocer's scoops upon a new and interesting plan. They are made of three-ply wood, the middle stratum or layer being placed with the grain of wood running at right angles to that of the two outer layers. They are finished with two heavy coats of orange shellac. These scoops will not curl up, like tin, when striking a nail, and they are free from rust.

BATH, Maine, is said to be the greatest wooden shipbuilding place in the world.

GOOD HEALTH.

Is Fat an Indication of Disease?

It has been held by some that "fat in animals is nothing but decomposed and diseased flesh"—"nothing but a mass of scrofula." Some people have ever refused to fatten their horses, "because fat is a disease." Now, fat is simply an oily, concrete material, secreted in various portions of the body. In swine, the abundant secretions about the kidneys are always denominated leaf-lard, or leaf-fat. Similar deposits in horses and neat cattle are called tallow. Nearly every one understands what fat is. A correspondent of the *Phrenological Journal* says:—"The chemical constituents of lard, or fat, consist chiefly of carbon and water. Fat is secreted in different parts of the animal and human body for two purposes, viz, nourishment and combustion. When a hen, goose, or duck enters the period of incubation, she is usually fat; but at the expiration of incubation she will be thin, and sometimes very poor. This fact shows that she has subsisted on her fat during incubation, most of the fat having been consumed to generate animal heat. If that fat had been "disease" or "a mass of scrofula," would it support animal life? Bears, skunks, raccoons, and many other wild animals usually become very fat during warm weather; and thus go into winter quarters, where they subsist entirely on their fat. When the spring returns they crawl from their refuges, lank and emaciated, as their fat, which has been their chief source of nutrition and warmth, is nearly all used up. If diseased tissue were to be absorbed and enter into the circulation (without the presence of any natural food in the stomach and bowels) would it sustain healthful existence; and would such diseased material maintain the natural heat of the body?"

Gangrene is a disease. Putrid flesh is a disease. Such substances will not sustain healthful life. If suffered to remain in the system they will impart their deleterious influences to the early extinguishment of life. Not so with fat. That substance is a sustainer of life as is shown by the above quotation. True, these may be an excessive accumulation of fat, so far as to obstruct locomotion, or seriously or even fatally interfere with the functions of life, as about the heart, liver or kidneys; but fat of itself is neither a disease nor the indication of a disease.

TREATMENT OF SCIATICA.—This troublesome disorder may be often cured and greatly relieved by a resort to the Turkish bath; but as that is often out of the reach of the patient, a good substitute may be found in very hot compresses. Wring out at night, before going to bed, a large towel wet in water as hot as can be endured, and ferment the parts over the affected nerve for half an hour. After the fermentation rub the parts vigorously with the hands, and cover with thick flannel for the night. Persevere with this treatment for several days, and the patient will generally be richly rewarded in a greater or less release from the trouble.

Clogging of the Blood.

People often speak of the blood as becoming clogged, and the expression is a very expressive one, but few have ever seen the process with their own eyes. And yet it may easily be observed by almost any one who has a microscope. To do so, catch a small tadpole, or pollywog, or, better, several, and keep them on hand in a glass vessel of water in which some plants are growing, so they may be handy when you have a little leisure to devote to their study. When you wish to place one under a microscope, take a glass tube of proper size, open at each end, and gently introduce it into the water directly over the young animal, taking the precaution to hold the thumb on the upper end, to prevent the entrance of the fluid into it. As soon as the tube is in the right position, remove the thumb, so the water may enter, which it will do with a rush, carrying the tadpole within. Now, replace your thumb and bring the tube to your eye box, in which the little fellow is placed, with sufficient water to keep him alive. Put on the cover and press it down, so as to hold the animal gently in position, otherwise he will wriggle about too much, and put the slide under your microscope. You will, with a low power of 100 diameters, or even less, see the circulation of the blood in the capillaries. It is a beautiful and instructive sight. These little tubes, when magnified a hundred times, look no larger than a fine cambric needle. They are filled with a transparent fluid—the serum of the blood—in which are millions of red and white blood corpuscles, the former, of course, greatly in excess of the latter. These look like so many discs and balls coursing after each other leisurely. The red ones, in Indian file, follow the center of the stream, while the white ones go nearer the wall of the vessel, and more leisurely. A very little pressure applied to the cover often stops, in one or more of the capillaries, the flow of blood, and then you may see, on a small scale, how the red and white globules stop flowing on as before and begin to dam up the vessel, and by and by all the other vessels get filled up, and the flow of blood is mostly at an end. Remove the pressure, keeping your eye on the plate, and instantly there is a rush of blood, just as there is in a stream when a dam gives way, and in an instant the congestion or clogging is at an end.

What happens in this little animal in this case on a small scale, is just what happens in a human being on a larger scale if pressure is applied to any part; as, for instance, in the feet, when the shoes are tight, in the skin about the forehead when the hat presses close to it, about the waist when the dress is close fitting, and so on. We will not go so far as to say that every one should own a microscope, for, without a teacher, only a few can use it to great advantage; but, with a few lessons in the beginning, one may get a great deal of pleasure and information from it. —*Herald of Health.*

VALUE OF SUNSHINE.—There is a vital relation between sunshine and the human body. Living in the shade is a prolific source of disease among women. A potato grown in a cellar is pale, sickly and worthless; expose it to the sunlight and it begins to show color, strength and power. Rear your daughter in the parlor, and she is pale and sickly; expose her to the sun, and its health-giving, direct rays soon commence to influence her health; keep increasing the daily amount, and from the invigorating sunshine she soon gathers health, strength and beauty. From experiments made with difficult diseases, I find the truest science of success lies in the use made of sunshine. Would poor, suffering women be galvanized into health, let them expose themselves daily for hours at a time to these life-giving rays (if possible without clothing,) always protecting the head by a shade, while the remainder of the body is drinking in vitality, and, other things being equal, health is sure to bless the effort. —*Dr. Larkin.*

SIMPLE CURE FOR COLD FEET.—The following remedy for cold feet is recommended by the *Fireman's Journal*, for sedentary sufferers, as well as policemen, car drivers, and others who are exposed to the cold: All that is necessary is to stand erect and very gradually to lift one's self up upon the tips of the toes, so as to put all the tendons of the foot at full strain. This is not to hop or jump up and down, but simply to rise—the slower the better—upon tiptoe, and to remain standing on the point of the toes as long as possible, then gradually coming to the natural position. Repeat this several times, and by the amount of work the tips of the toes are made to do in sustaining the body's weight, a sufficient and lively circulation is set up. A heavy pair of woolen stockings drawn over thin cotton ones is also a recommendation for keeping the feet warm, and at the same time preventing their becoming tender and sore.

THE ANNOYING HOUSE FLY.—In addition to the other annoyances connected with the presence of the common house fly, Dr. Thomas Taylor, of Washington, D. C., has made some investigations, from which it would appear that that insect is possessed of the capacity for transmitting disease by carrying the germs from place to place. This fact has long been suspected, but we know of no careful experiments having been made to establish the facts in the case.

Passing Events.

There is very little new to report from the mining regions aside from what we have noted in our "Mining Summary." Work is going on nearly everywhere with renewed vigor as the days lengthen. Relocating has placed many prospects into more industrious hands this season, many of which we expect to hear from satisfactorily before long. Up in Idaho, prospecting and mining operations are beginning at least six weeks earlier than they did last season. Already many prospectors have struck into the bills, and many mining operators have returned. Important sales and transactions have taken place during the winter. The same is the case in other localities. The Indian troubles in Arizona are keeping that region back some by deterring the prospector, but the energetic people there will not allow such a state of affairs to last long if the military authorities do not succeed in quelling the disturbances.

The old Spaniards of 300 years ago took out vast amounts of the precious metals near Santa Fe N. M. Among the curious things to be found are the old Mexican ladders still to be seen in some of the mines, and the remains of the old arastras and furnaces made by those ancient miners.

The Castilian Mountain, near Cerrillos, New Mexico, has been worked for hundreds of years and produced some of the finest turquoises found in the world, except Persia.

Swelling and Bottom-Breaking Ground.

Most miners have on occasions had trouble with swelling or bottom-breaking ground. In some camps there is more trouble from this than in others, of course according to the nature of the formation. When it occurs, however, it requires very skillful and careful timbering to prevent accident. The cause of bottom-breaking ground is given by Mr. Henry S. Drinker, in his elaborate work on "Tunneling," when occurring downward, as being in the majority of cases due to hidden caves or sink-holes as in limestone formation. Breaks at bottom occurring upward, he says are the cases where the ground is so heavy, that though the sides and roof may be firmly held, the material is so running as to be semi-liquid, and therefore transmits the side pressure around, and so forces up the tunnel or drift bottom where it is not properly secured by an invert.

In one of the tunnels of the Cincinnati Southern R. R., the curious fact was noted by the resident engineer, that it would not only fall from the roof, but would not stay down in the bottom. The bottom was a hard tough sandstone in layers of four to eight inches thick. These layers would, with a rumbling sound, spring up and break into pieces with a report like a small blast. This would happen sometimes after no work had been done in the tunnel for several days, so that it could not be attributed to the effects of powder. One or two layers would generally come up, breaking off at the wall and then the springing cease. These ledges came up with such force, that men sitting on them, would be thrown over. In one instance a sill, on which posts for timbering were set, was put in on the bottom; the sill extended seven and a half feet beyond the last post, which was lagged and packed overhead, so that at the post, the sill was immovable. One of these ledges springing up, forced this sill—a piece of 8x12 with white oak—up out of its position six inches in seven and a half feet.

Similar phenomena have been observed in the granites at Munson, Mass., and in the lower carboniferous sandstone of Ohio. It is probable that the cause of the break is owing to a state of tension existing in the rock or place; then, when the strata are cut, a tendency to wrong results.

In cutting the Suto tunnel much trouble was occasionally experienced from bottom breaks, more, however, from swelling ground. This was usually met in the roof by extra timbering, while the bottom was simply allowed to rise until it reached a certain point where it is cut down again repeatedly.

At a point 17,890 feet from the tunnel mouth they entered a belt of swelling ground composed of porphyry and clay, which was very difficult to penetrate. The rock swelled to such a degree that timbers 14x18 inches thick would be broken three hours after they were placed, and, although a gang of men were kept at work easing up behind the timbers, they were continually breaking, and it was exceedingly difficult to make any progress. Not only did the timbers break but at times the posts would press through the caps. For a long time they could suggest no means to withstand the pressure, but finally a new plan of timbering was devised which proved successful.

They first placed the ordinary 12x16 inch square set of timbers, and then made an excavation above the cap, in which they placed two angle braces meeting at an apex. By this means the great pressure from above was prevented from coming directly on the caps, it being taken up by these angle braces, upon which it was exercised first. They were thus pressed gradually into the sides of the tunnel until the apex at which they met was finally forced down close to the caps. When that time arrived they were dug out and placed again. In this manner the main timbers were saved, and since they placed two-inch lagging on top of these braces and three-inch lagging on top of the main caps, the men were protected from falling rocks, and the work could progress without delay. The lagging above the upper set was purposely lighter than that over the main lower set, so as to allow it to break and give the ground a chance to swell behind. Extra posts were placed in order to protect the main posts, but no sills were used in such ground, for they would be constantly breaking. They simply allowed the ground in the bottom to swell up until say eighteen inches above the proper

level, when it was cut down and the railroad track re-laid. After passing through the swelling ground at the point referred to they had to cut it down seven times, that is to say, the bottom of the tunnel at this point was cut down seven times eighteen inches, or ten and a half feet. The most of the swelling ground extended for about 300 feet; the total distance of had ground extended over 100 feet.

Sediment in Mining Streams.

In the last number of the MINING AND SCIENTIFIC PRESS was given a method of determining the amount of sediment held in suspension in streams. The subject is quite an important one here in California, where mining is done near the streams. Yet it is little understood by people who ought to know, as was very fully shown by the conflicting statements made concerning it in the recently-tried case of Woodruff vs. the North Bloomfield Mining Co.

One engineer swore that there were 45,000 cubic yards of solid matter moving down the Yuba past Marysville. He estimated that three and a half per cent. is carried in suspension by the Yuba past Marysville. The same man swore that three times as much "crawls" along the bottom of the river. Figuring from this data, there results 580,000,000 cubic yards of sediment passing Marysville per annum. The total hydraulic mining excavations on the Yuba watershed are, according to the same engineer, 176,000,000 cubic yards; hence, if his data had been correct, more than three times as much sediment is discharged into the Feather river from the Yuba each year than has been excavated from all the mines on the Yuba river watershed since the year 1849. Another man (on the same side of the case) took a sample at the same time, and found it to contain by weight 1.23 per cent. of sediment. This, reduced to volume, gives .64 of one per cent. of sediment, or about one sixth of the percentage fixed by the other engineer's experiment.

Two other engineers took samples of the Yuba river water opposite Marysville in October last, in the most careful manner; and as a result determined the amount of sediment in suspension at the same point where the other experiments were made, to be 19-100 and 12.100 of one per cent., as fixed by two separate samples.

With all the data at the command of the State Engineer, he was unable to show how much of the material mined in the past had gone down into the valley, and how much had remained in the mountain streams. What percentage of the material removed from the hydraulic mines comes down into the valley, it is impossible for any one to state with exactness, there not being sufficient data at hand to enable any engineer, no matter how competent, to make an exact estimate. Such data could be only obtained by elaborate surveys requiring several months' time. In making an estimate of the debris remaining in the Main Yuba, South Yuba, and Middle Yuba, the State Engineer concludes there are 29,870,000 cubic yards, while another engineer estimating on the same river makes the amount 21,507,000 cubic yards. Thus, in less than 30,000,000, there is a difference of over 8,000,000, or about 40% in the estimate. And when it comes to calculating on debris in suspension, the differences in estimate are even greater.

A RUSH FOR COPPER ORES.—Santa Fe district, Esmeralda county, is fast opening a very large area of copper mining. There are a great many prospects in that section of the country, nearly all of which are being worked more systematically and energetically this season than at any previous time. Some very pretty specimens were brought in this week, and very flattering accounts are told of quite a number of fine looking properties. Several smelters will necessarily have to be erected at an early date, each of which will cause more search to be made for copper ore, and assist the settlement of this fast becoming noted mining section of Nevada.—*Candelaria True Fissure.*

BELOW the Gold Valley Tunnel and Mining Co.'s ground, which is two and a half miles from Scales Diggings, Sierra Co., there are two debris dams, one mile apart, built by the mining companies of the northern part of Sierra county and southern portion of Plumas county. These companies have consolidated and bought the tailings claims in Slate creek, paying therefor \$15,000. The dams are eighteen feet high on the lower sides, and can be raised to 100 feet in height if necessary. They are capable of holding the debris from a great many mines for years to come. This is one practical way of settling the debris question.

New Mine Surveying Instrument.

Most mining engineers have experienced the unsatisfactory nature of the ordinary transit, when applied to certain work about mines, and have had difficulty in placing it in proper position for vertical sights. Mr. Robinson Gibbons, of this city, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency an attachment for transits and other surveying instruments, which renders it possible to direct the telescope to a point beneath the instrument.

Mr. Gibbons uses the ordinary plate which usually supports the telescope of a transit or other surveying instrument, having the needle-box, graduated divisions, verniers and other attachments usual to such instruments, and a means for mounting it upon a tripod or other support. He has devised, however, a supplemental plate, formed preferably in the arc of a circle, so as to coincide with the main plate upon which it is supported. This supplemental plate is hinged to the other one at one side, and when let down upon it is parallel or level with it. The standards upon which the telescope is mounted are secured to the supplemental plate so as to partake of its motion.

As before stated, the supplemental plate is hinged at one side to the main one. At the opposite side of the main one is a vertical arc passing through a slot in the hinged supplemental one, and a clamp is arranged to hold the swinging plate at any desired position on the arc. This arc is jointed at the bottom, so that when the supplemental plate is horizontal in the main plate, the arc may be folded down out of the way for the ordinary operations of the instrument.

Wherever it is desired to use the telescope at an angle more nearly vertical than can be attained upon the main plate, or support as ordinarily constructed, the supplemental plate is lifted about its hinge and the clamp screw fixed so as to hold the supplemental plate rigidly to the arc, when the telescope may be made to assume a vertical position to one side of the main plate, so one may look down vertically.

The device is especially useful in laying out the direction of an underground drift in a mine upon the surface. In such a case, the instrument may be set above a shaft, and the telescope turned down, so that two points may be determined upon a line which leads across the shaft and into the drift. This avoids the danger of mistake on account of an aberration of the compass, which often occurs below ground, and the direction being once fixed, the remainder may be made to correspond upon the surface and below. When not in use, the supplemental part may be folded down out of the way. The device is quite effective.

The Late Peter Cooper.

The Mechanics' Institute, at a special meeting Saturday night, adopted the following upon the death of the venerable philanthropist, Peter Cooper:

WHEREAS, Intelligence has reached this Society of the death of the venerable Peter Cooper, whose works of beneficence toward the working classes are well known, and who in founding, maintaining, and guarding, for twenty-four years, the Cooper Institute, in addition to other works of beneficence and philanthropy, evinced a consciousness and scrupulous regard for the well-being and future prosperity of many thousands of young citizens and mechanics, as well as an appreciation of the condition of the working classes; it is

Resolved, By the Mechanics' Institute, in meeting specially called to recognize the fact of the death of our friend and benefactor, Peter Cooper, that we recognize in his life an example of what a noble and good man can do for the benefit of his fellow-men during his lifetime; that we recognize in the death of Peter Cooper the inevitable fact that death must come to us all, but that the death of such a man is an irreparable loss to the people at large, and more especially to the mechanic and workman of America. We further recognize the fact that the beneficent acts of Peter Cooper during his life are more emphatic in their own praise than any words of ours could be, and more enduring than any monument we could erect. We, therefore, simply thank God that such a man lived, and desire to express our humble submission to the fact of his death and our loss.

Resolved, That the above preamble and resolutions be spread upon the records of this Society.

The resolution was ordered to be spread upon the minutes of the Institute, and a copy was ordered engrossed and sent to the family of the deceased. Several gentlemen made short and eulogistic addresses, and the meeting adjourned.

THE General Custer mine, at Custer City, Idaho, in the Yankee Fork district, has been running a twenty-stamp mill since January 1, 1881, and since that time has produced an average of about \$70,000 per month in gold and silver bullion.

English Investments in the Pacific Coast Mines—No. 1.

[Prepared for the MINING AND SCIENTIFIC PRESS by H. DEERROOT.]

Total Expenditure and Results.

It is now about twenty years since English capital began to be invested in the mines on the Pacific coast. Commencing with the gold mines of California, these ventures were gradually extended to the silver mines of Utah and Nevada, some limited investments having meantime been made, also, in Oregon, the foregoing being the only countries of which any note will be taken at this writing. While the sum total that has been so invested can be only approximately arrived at, it is known to have been large, reaching not less than \$30,000,000. By this we mean money actually expended in the purchase of mining properties, and in equipping and improving the same, the money that may have been lost through speculations in this class of mining shares on the English market not being included in the above estimate. And here it may be observed that the capital stock of these English companies consists of actually paid up shares, it not being the practice there to organize companies with an absurdly large, but mere nominal capital, as, to our discredit, is done in this country.

Of the money actually expended by these English investors, about three fifths—say eighteen million dollars, have already proved a total loss, one fifth having turned out tolerably good and the remaining one fifth a first-class investment; in the category of the tolerably good, there being included a number of properties, which, while they have not as yet yielded any profit, promise to do so, some of them in the early future. Why so large a proportion of these ventures have proved failures will be noted as each particular case comes to be considered, some remarks bearing on the same point, but general in their application, being added after our review of the history of these enterprises has been completed.

The first enterprise on this coast undertaken by English capital was the construction of the Truckee canal, built to take water from the Sierra Nevada and convey it upon the divide between the North and the Middle Forks of the Yuba, in Sierra county, California. This canal was completed in 1858, at a cost of \$1,000,000, nearly the whole of which was lost to the original investors. A more ill-advised work was never constructed nor even projected, the canal, which had a large carrying capacity, ending in a neighborhood noted for its limited water requirements. On this divide there were scarcely any hydraulic deposits—only drift diggings, and these at the time pretty well exhausted. There being here no demand for this large supply of water, and it being well nigh impossible to conduct it to points where it could be sold or profitably employed, the company were forced to abandon their ditch, which being neglected, soon after became a total ruin. The sum of \$50,000 realized from the sale of their water franchise was all that these first adventurers in the mines of California saved out of their heavy investment.

More Fortunate Ventures.

In the summer of 1869 an English syndicate bought and came into possession of the Sierra Buttes quartz mine, situate thirteen miles east of Downieville, Sierra county, paying for the same, according to report, the sum of \$1,000,000. The purchase was capitalized at \$1,225,000, the stock consisting of 122,500 shares of the par value of \$10 each. This property has paid dividends, with the exception of six months or one year at the most, from the time it was bought to the present. After the custom in England, this company has adopted the plan of declaring their dividends semi-annually. The sum total disbursed to the shareholders amounted in October last, to \$1,429,683. For several years at first, while the ore remained of a tolerably good grade, the mine made net earnings at the rate of twenty per cent. per annum on the amount paid for it; latterly the ore has so deteriorated that such earnings have not exceeded five or six per cent., having amounted to only fifty cents per share. For a number of

years past the net proceeds of the mine have varied from fifty-five to seventy-five thousand dollars per annum. Just now it is hardly clearing the smaller of these sums, as much money requires to be expended in searching after and opening up new bodies of ore.

The Sierra Butte shares are now quoted on the London market at \$7.50 each, a figure at which it is thought they can be maintained, the prospect for an early improvement in the quality of the ore being considered good. Besides a steady impoverishment of their ores, which yield now hardly more than \$5.50 per ton, this company have met with some other setbacks of late. One year ago their principal mill was totally destroyed by a snow slide. This accident, besides necessitating the building of a new mill, to be put up the coming summer, has since seriously curtailed the productive capacity of the mine. For several years past an immense amount of dead work has been in progress here, and some of which will require to be kept up for a year or two more. A part of this work consists of a long tunnel carried in on a lower level than any heretofore driven. All the ore thus far has been taken out through tunnels, no hoisting works having until recently been erected here, those now in use being employed to lift the ore after it has been brought out through the tunnels up to the mills, the latter being now considerably above the level of the lowest tunnel run. The mills heretofore built have been placed high up against the side of the mountain. The new mill about to be put up will be located down on the river, and at a point so low that the ore hereafter taken from the mine will be carried to it by the force of gravity. There are now 50 stamps running on the ore from this mine besides some 35 or arastras, the whole being driven by water. These arastras, which are employed in working over the tailings are owned by outside parties, who pay the company a percentage of the gold taken out. The new mill, also to be propelled by water, will be built with a view to subsequent enlargement, there being always water enough in the North Yuba river, on which it is to be located, to drive almost any required number of stamps. The cost of extracting and milling the ore here amounts to not quite four dollars per ton, a good deal of this being due to the large amount of dead work that for some time past has been in progress. This company employs an average of 220 men, about three fourths of them in the mine.

This property comprises a number of quartz lodes varying from 30 to 50 feet in width and carrying large ore chutes distributed irregularly through the vein matter. The Sierra Buttes was among the first quartz mines ever worked in the State, operations having been commenced upon it with arastras as early as 1852, from which time up till 1857 it turned out about \$250,000. From 1857 to 1860, inclusive, the gross production made here amounted to \$1,835,525, of which \$1,139,000 were disbursed in dividends. All the expenses incurred in working and improving the mine, plant included, were met from the net proceeds.

In 1872 this same syndicate bought another and similar property, known as the Plumas Eureka, and for which they paid about the same sum as for the Sierra Buttes mine. This second property, which is located in Mohawk valley, Plumas county, had up to the time of its purchase produced nearly \$2,000,000, over a fourth of which had consisted of net profits.

The new company organized with a capital stock of \$1,406,250, divided into 140,625 shares, of the par value of \$10 each. From the year of their organization up to 1881, with some slight intermissions, they paid an annual dividend of \$1.50 per share, which dividend for the past two years has been reduced to \$1 per share—one half the above rates of dividends having been disbursed semi-annually. The sum total of dividends paid to date amounts to one and a half million dollars. The present rate of net earnings can, it is believed, be kept up here for an indefinite period, certainly for a number of years to come.

This is beyond any question a valuable property, the mineral deposits consisting of three powerful lodes, each containing large masses of ore of moderately good grade; that worked of late years having yielded an average of about \$7 per ton. Cost of extraction and working, \$3.25 per ton; the quantity raised ranging from forty-five to fifty thousand tons yearly, as at the Sierra Buttes. The ore here is taken out through a series of tunnels, the one below the other, and by means of which the several lodes can be worked and drained to a depth of more than a thousand feet. For ore reduction purposes a sixty stamp, water-driven mill has been provided, an old mill built some years since being no longer in use. The new mill, in every respect a superior structure, occupies an eligible site, being located so far below the mine that the ore will for a great many years be carried to it by the force of gravity. For preparing and grinding the tailings a large number of concentrators and arastras have been placed below the batteries. A great deal of dead work has latterly been done at this mine. As less will be required in the future, the cost of billion production will undergo a corresponding diminution.

A year or two since, the ore chutes in the river tunnel became so broken up that it was deemed advisable to drive a tunnel on a still lower level, in the hope that it would develop

The Payne Portable Engine.

The engraving given herewith represents the Payne automatic cut-off portable engine, arranged for straw-burning and field work. This engine is not complicated, and every part is easily accessible. The material is so distributed as to give a perfectly balanced engine. The heat passes twice through the boiler, and is utilized in heating the water instead of passing up the stack. The manufacturers claim that this is the safest boiler in the market. The return flue and spark-arresting chambers give almost entire safety from sparks, and absolute safety when the engine is not crowded and made to develop more power than it is rated at. The construction is of the best. The wearing parts are easily renewed or taken up. The boiler, which needs more care than any other part, but which generally receives the least, is easily gotten at. By raising the doors at both ends, the flues are completely exposed, and easily cleaned or repaired.

The governor is Tabor's patent automatic cut-off, the eccentric rod of which is attached directly to the valve stem, so that whatever change is effected in the eccentric is transmitted at once to the valve. One feature of this governor is particularly valuable. In case of breakage, the eccentric is immediately carried to a position of minimum throw, and the engine stopped at once. Should the drive belt break, or be thrown off the pulley, a corresponding action takes place. Any change in resistance applied to the wheel is accompanied by a corresponding change in expansion. There is no throttling or wire drawing of steam, such as is experienced by the ordinary governor. The advantages of using steam expansively are many. To receive the full advantage of expansion, however, the steam should be admitted to the cylinder at boiler pressure and cut off sharply at such a point as will enable it to overcome the resistance applied and maintain the required speed. This can only be done with the automatic cut-off, where the governor is applied directly to the cut off valve. To effect this result the device known as Tabor's automatic cut-off is employed.

Messrs. H. P. Gregory & Co., of 2 and 4 California street, in this city, who are sole agents for this coast,

inform us that the new engine will work, under favorable circumstances and with attention, at the rate of three and eight tenths pounds of combustible per transmitted horse power per hour. It is expected that the engine will keep up to this standard in ordinary use with the usual ease but properly fired they may be worked with about three and a half pounds of good coal per horse power per hour, equal to the usual rate of first-class stationary engines.

The circular states that a series of careful tests, extending over several days, gave the following results from a ten horse power engine. The transmitted power was determined with the friction brake, constantly lubricated with water. Indicator diagrams were taken every 15 minutes, as were, also, the tension on the brake, number of revolutions per minute, and the steam pressure.

Engine—Seven-inch bore, 8-inch stroke. Boiler—Return tubular, 32 inches diameter, nine feet long, 17 three-inch flues seven feet long; fire fine eighteen inches diameter, seven feet long.

Average number of revolutions per minute..... 279.9
Average boiler pressure, lbs..... 80.5
Average tension on brake, lbs..... 149.58
Average transmitted horse power..... 13.499
Average coal consumed per transmitted horse power per hour, lbs..... 4.22
Combustible per transmitted horse power, lbs..... 3.8
Water evaporated per lb. of coal, lbs..... 9.25
Water consumption per transmitted horse power per hour, lbs..... 29.
Average indicated horse power..... 15.98
Average coal per inch horse power per hour..... 3.57
Average combustible per hour..... 3.22
Actual water consumption per inch horse power per hour..... 33.
Average m. e. p..... 36.84

The cylinders are jacketed, and have a balanced valve; all wearing surfaces are large, carefully fitted, and adjustable, wherever adjustment is required; the arrangements for oiling the working parts are convenient and complete. All engines are thoroughly tested before they leave the shop. A friction brake is used; indicator diagrams are taken at different pressures; a speed indicator is attached to the engine and the speed regulated.

CHICAGO FRASER & CHALMERS. ILLINOIS
MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF
MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST AP-
POINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's &
Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our
patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved
forms. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other
adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.
HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 6,000 feet long;
Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS
of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otto Steel. Workmanship the most careful. All
Rivets Hand Driven.

This latter size furnished J. B. Haggin for Grant and Old Abe Co., Black Hills
also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD
AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical
in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours
with 30 H. P. For circulars and full particulars apply to or address,

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Glo-
sary. Explains how to examine mining titles. Contains
numerous court decisions. Gives the Public Land Com-
missions Codification, and gives many and improved forms.
Price—Full law binding, extra paper, 650 pages, \$6.00.
For Sale by DEWEY & CO., San Francisco

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and
Quartz sluices, which is proving very efficient, below
everything else. (Cost six cents per pound.) Address,
ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 26, 1883.

Mr. A. B. Paul:—I have tried your Riffles thoroughly,
and find them a fine Riffle. They are good with quick-
silver or without. They gather the fine gold and rusty
gold. I find gold that will not touch quicksilver stops in
them and which slides over 300 feet of sluice above them.
I shall try 30 more, and if they save the same amount of
gold in four weeks' run, I shall want 100 more. I am not
afraid to vouch for them. B. G. McLean,
Superintendent Indian Spring Drift Mine.

 NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

BRACE FOR AXLE SPINDLES.—Robt. R. Spedden, Astoria, Oregon. No. 274,230. Dated March 20, 1883. This brace for axle spindles consists in the details of construction of a rod or bar attached by one end to the axle and by the other to the end of the spindle, its intermediate portion passing around or over the rim of the wheel. The object is to strengthen the spindle without increasing the friction, whereby a smaller spindle may be used, which will have as much strength as, and less friction, than a larger one without a brace.

MAGAZINE GUNS.—John P. Simmons, S. F., and Samuel Adams, Antioch, No. 275,085. Dated April 3, 1883. This invention relates to certain improvements in breech-loading small arms of that class known as "magazine guns," and it consists in an improved construction of the breech mechanism, so that the cartridge is taken from the magazine, and carried up and inserted into the barrel, the follower is locked when in place, and the gun is cocked, all by a novel mechanism. The movement of all the principal working parts are direct and positive, and no springs are employed to assist in any of the movements.

DIRT SCRAPER.—James Porteous, Fresno, No. 275,075. Dated April 3, 1883. These improvements in dirt scrapers consist in a means for limiting the throw or dump of the bowl, whereby the tail lever or handle is prevented from striking, or getting in the way of the horses, and in a means for raising the edge or bit of the bowl when in this limited dumped position, in order that it may not drag along the ground.

SELF-REGULATING WINDMILL.—Geo. K. Glenn, Woodland, Yolo county, assignor of one half to Hall & Bidwell, same place. No. 275,036. Dated April 3, 1883. The arms are made self-regulating, so they may adjust themselves to the intensity of the wind. The object is to provide a simple, self-regulating windmill, and the object is attained by adopting an old and simple form of mill, and by means of simple changes and devices, convert it from its old and objectionable shape to an effective self-regulating mill.

DYSPEPSIA, the bug-bear of epicureans, will be relieved by Brown's Iron Bitters.

THE Chicago and Northwestern Railroad has issued a statement showing it has in operation and under construction a total of 5,000 miles of road.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year.

N. B.—Personal attention will be called to this (as well as other notices, at times) by turning down a leaf.

Pacific Business College.

The Pacific Business College, beautifully located at 350 Post street, S. F., opposite Union Square, is enjoying merited prosperity. A host of young men from all parts of the coast are to be found here, rapidly preparing themselves for entrance to business life. The institute is worthy the attention of those seeking an acquaintance with business methods of the most approved order. The courses of study have been specially prepared to meet the requirements of a business life, and are thorough and practical. In the commercial course, a system of actual business is employed, combining theory and practice, and is at once so simple and natural that it needs only an explanation of its merits to convince the most skeptical of its superiority over all other systems. Book-keeping in all its departments, and the collateral branches included in the business course, are taught in the most thorough and systematic manner. The academic course is designed to give regular and systematic trainings in the English and advanced mathematical branches, and to prepare those who need elementary education to enter upon the commercial course with a better foundation, and with more certainty of success. In the business course, the class system is entirely discarded, except for general reviews and practical exercises on the blackboard. Students receive such individual instruction in the several departments as to enable them to pursue their studies as rapidly as their ability will admit. No student, therefore, is kept back in his course by those of less ability and application. On the contrary, he is always advanced as rapidly as is compatible with thoroughness. Those who have not had the advantages of education in youth will here find the readiest means of supplying their deficiencies. Ladies are admitted into all the departments of the college on an equal footing with young men. They receive the same instruction, and have in every respect the same advantages as the other sex. The Pacific Business College is recognized as one of the substantial institutions of California, and affords excellent facilities for acquiring a thorough business education. The proprietors, Profs. Chamberlain and Robinson, are practical men and first-class educators in the line they have chosen to work.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANES, State Mineralogist.]

[CATALOGUE.]

4804. White Sand—Thirty-two feet from the surface, near Lincoln, Placer county, Cal. In its natural state. (See No. 379.) John Landis.
 4805. White Sand—Thirty-two feet below the surface, near Lincoln, Placer county, Cal. The same as No. 4804, but washed. John Landis.
 4806. White Sand—Found 32 feet below the surface in the Clippert coal mines, near Lincoln, Placer county, California (see No. 4804). John Landis.
 4807. White Sand, Washed—Found 32 feet below the surface in the Clippert coal mines, near Lincoln, Placer county, California (see No. 4804). John Landis.
 4808. Clay—Found below the coal beds, 75 feet below the surface, Clippert coal mines, near Lincoln, Placer county, California. John Landis.
 4809. Washed Clay—Found on the sand stratum, 30 feet below the surface, Clippert coal mines, near Lincoln, Placer county, California. John Landis.
 4810. Ironite—Clippert coal mines, near Lincoln, Placer county, California (see No. 382). John Landis.
 4811. Lignite—Clippert coal mines, near Lincoln, Placer county, California. This material has not yet received the study it deserves. It very much resembles ironite which has been analyzed, and while it has the appearance of being a very inferior lignite, it serves many useful purposes as a fuel, and is contained in large quantities in the neighborhood. John Landis.
 4812. Water from Owens' great lake, Inyo county, California. S. D. Woodhull.
 4813. Chalcedony—Upon the surface of which are stellar aggregations of the binoxide of manganese (?) (see No. 2107). Aurora, Esmeralda county, Nevada. F. W. Smith.
 4814. Red Brecciated Jasper—Near Aurora, Esmeralda county, Nevada. F. W. Smith.
 4815. Model of a Gold Bar—The result of one run made in the North Bloomfield hydraulic mine, Nevada county, California. Wei, bit, 6,127.5 ounces Troy; gold, fine, 897; silver, fine, 93; total value, \$114,281.72. This is probably the largest gold bar ever cast in the State. Presented by Henry G. Folsom.
 4816. Eulima Subulata (Desh.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4817. Canellaria Umbilicaria (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4818. Venus Scalaris (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4819. Murex Tapparonii (Bele.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4820. Venus Scalaris (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4821. Soleculius Constatatus—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4822. Trochus Patulus (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4823. Arcu Nole (Linn.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4824. Terebratulina Grandis (Blum.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4825. Corbula Gibba (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4826. Phorus Orisopus (Kon.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4827. Solenaster Simplex (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4828. Cymbella Euthrostroma (?)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4829. Trochus Patulus (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4830. Niso Tebellum—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4831. Dillia Brochii—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4832. Venus Rostatus—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4833. Fucosia Fimbriata (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4834. Fucus Clavatus (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4835. Murex Scalaris (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4836. Mitra Striata (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4837. Canellaria Mitriformis (Broch.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4838. Cardium Papillosum (Foll.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4839. Murex Polymorphus (Brochii)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4840. Venus Callina (Linn.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4841. Polia Phicata—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.
 4842. Fossarus Constatum (Phil.)—Upper Pliocene Fossil, Hills of Asti, Alessandria, Northern Italy.

News in Brief.

THE population of Los Angeles is estimated at 20,000.
 THEY have formed a base-ball club in New York, and the players are all Chinamen.
 DIAZ is reported to have said that the so-called German land scheme in Mexico is wholly imaginative.
 THE most disastrous prairie fire that ever occurred in Nebraska was raging, Sunday, a few miles north of Lincoln.
 THE Spanish Chamber of Deputies has passed the bill permitting the substitution of affirmation for an oath, when desired.
 PRESIDENT ARTHUR, Secretary Chandler and Senator Miller, of New York, left Washington last week, for Jacksonville, Fla.
 THE Raymond excursion party, consisting of 150 Bostonians, has left Chicago via Rock Island for San Francisco and the Pacific coast.
 THE Russian police believe that unless liberal reforms are granted the Nihilists have determined to prevent the ceremony of coronation.
 THE farm of ex-Governor Don Pio Pio was sold at Los Angeles, Saturday, for \$60,000. It was purchased by an association and is to be subdivided and sold in small farms.
 A ST. PETERSBURG dispatch says: The local Chief of Police and all others who contributed to the comfort of the crews of the Jeanette and Rodgers have been decorated by the Czar.
 In the British House of Commons Jacob Bright introduced a resolution, which was adopted, against any power exercising dominion or privileges in the Congo country to the exclusion of others.

THE Central Pacific Company propose to demonstrate whether the grape industry can not be made profitable near Reno, by the planting and care of ten acres in vines on the hill near the reservoir.

THE railroad survey up Snake River, I. T., has progressed fifty-one miles. They are now in the hardest part of the canyon. Chief Engineer Clark is with the party coming down. The instructions are to hurry the survey and lay the grade stakes as they proceed.

THE New York Mail and Express says: The immigrant lists for the week closing Saturday have not been so large as the season would warrant or was expected. This is due, it is thought, to the action of European agents in booking steerage passengers through to California and the West, by way of New Orleans, at \$35 a head.

THE Immigration Association reports the arrival of 1,078 immigrants during the past week. Of this number 709 came by the Central Pacific Railroad, and 359 by the Southern route. Eight hundred and thirty eight were males, and 240 females. A number were married men who came out in advance of their families.

AS WILLIAM FENDER was walking down the mountain side at Highland, Lake county, a sudden gust of wind caused him to fall to the ground, and at the same time a half-felled tree fell upon him and caused such injuries that he died within two hours. His wife, when she learned of his death, went stark mad.

MRS. R. E. HEWITT, of Santa Ana, purchased from a traveling peddler a powder, which purported to be a specific against the explosion of coal-oil lamps when placed in the oil. Having no use for the powder, she threw it into the fire in the stove. Instantly a stream of fire shot up into the lady's face, burning her severely, though not dangerously.

SINCE the pest of phylloxera became so general, the adulteration of French wines has been so open and undisguised as to be thought a matter of course by commercial people, yet 18,000 wine merchants of the Department of the Seine held a mass meeting a day or two ago, and addressed themselves to the legislative and municipal authorities, asking that the abuse be corrected.

AN analysis of the contents of the stomach of John Dwyer, found dead in a lodging house in this city, on the 2nd inst., has been made, and William T. Wenzell, presented the following report to the coroner: "I have made a chemical and microscopical examination of the stomach and contents of John Dwyer, which show that his death was probably caused from eating mince pie containing tainted or partially decomposed meat. The chemical analysis demonstrated the presence of a poisonous cadaver alkaloid."

GEN. SHERMAN, when in June he starts upon his last tour as Commander of the Army, will not take ladies with him, as he has done hitherto, for the proposed trip will be altogether too rough a one for the ladies. They will go first to Detroit, thence through northern portions of the Territories, including the outposts in Alaska. Returning, they will visit California and the Yellowstone Park. They will not start until after Gen. Sherman has attended the graduating exercises at West Point.

The Secret

of the universal success of Brown's Iron Bitters is simply this: It is the best Iron preparation ever made; is compounded on thoroughly scientific, chemical and medicinal principles, and does just what is claimed for it—no more and no less.

By thorough and rapid assimilation with the blood, it reaches every part of the system, healing, purifying and strengthening. Commencing at the foundation it builds up and restores lost health—in no other way can lasting benefit be obtained.

75 Dearborn Ave., Chicago, Nov. 7.

I have been a great sufferer from a very weak stomach, heartburn, and dyspepsia in its worst form. Nearly everything I ate gave me distress, and I could eat but little. I have tried everything recommended, have taken the prescriptions of a dozen physicians, but got no relief until I took Brown's Iron Bitters. I feel none of the old troubles, and am a new man. I am getting much stronger, and feel first-rate. I am a railroad engineer, and now make my trips regularly. I can not say too much in praise of your wonderful medicine. D. C. MACK.

BROWN'S IRON BITTERS does not contain whiskey or alcohol, and will not blacken the teeth, or cause headache and constipation. It will cure dyspepsia, indigestion, heartburn, sleeplessness, dizziness, nervous debility, weakness, &c.

Use only Brown's Iron Bitters made by Brown Chemical Co., Baltimore. Crossed red lines and trade-mark on wrapper.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. A valuable and carefully written work. Postpaid, \$3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

U. S. MINING LAWS AND COAL LAND LAWS.—Containing instructions and blank forms. Postpaid, 50 cents. Sold by Dewey & Co., S. F.

COPP'S AMERICAN MINING CODE, to replace Copp's Handbook of Mining Laws, now out of print. United States, State and Territorial Mining Laws and Land Office Regulations; Digest of Land Office and Court Decisions; List of Patents issued, and Dr. Raymond's Glossary, with Form for Mechanics' Liens, Location Notices, etc. Price, postpaid, in paper, 50 cents. Sold by Dewey & Co., S. F.

THE EXPLORER'S MINERS' AND METALLURGISTS' COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 Pages and 83 Engravings. Price, bound in cloth, \$10.50. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

CORRESPONDENCE is cordially solicited from reliable sources upon all topics of interest and value to our readers.

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

NOTICE OF THE APPLICATION

—OF THE—

South Comstock Gold & Silver Mining Co.

For Dissolution and Disincorporation.

Notice is hereby given that the South Comstock Gold and Silver Mining Company has this day filed with the Clerk of the Superior Court, of the City and County of San Francisco, an application for Dissolution and Disincorporation, and all persons desiring to file objections to such application are hereby notified to file such objections within thirty days after the first publication of this Notice.

Silver King Mining Company

San Francisco, April 4, 1883.

At a meeting of the Board of Directors of the above named Company, held this day, a Dividend (No. 40) of Twenty-five Cents (25c) per share was declared, payable on MONDAY, April 15, 1883, at the office of the Company, Room 19, No. 323 Montgomery Street, San Francisco, Cal. Transfer Books will close April 7, 1883, at 12 M.

JOSEPH H. NASH, Secretary.

Buchanan Gold Mining and Milling Company.—Location of principal place of business, San Francisco, Cal.; location of works, Tuolumne, Tuolumne county, Cal.

Notice is hereby given that, at a meeting of the Board of Directors, held on the 3th day of March, 1883, an Assessment (No. 2) of Five (5) Cents per share was levied upon the capital stock of the Corporation, payable immediately, in United States gold coin, to the Secretary at the office of the Company, room 3, No. 121 Post street, San Francisco. Any stock upon which this Assessment shall remain unpaid on the 2d day of May, 1883, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on FRIDAY, June 1, 1883, to pay Delinquent Assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

P. J. SULLIVAN, Secretary.

OFFICE—Room 3, 121 Post Street, San Francisco, Cal.

NOTICE TO CONTRACTORS.

Sealed proposals will be received by the Brandy City Mining Company until May 1, 1883, to run a bedrock tunnel to its mining lands, situated at Brandy City, Sierra County, Cal., near the town of Camptonville, Yuba County. Said Tunnel to be about 3,000 feet long, 6 feet wide and 8 feet high, with a grade of 5 inches to every 12 feet. Water Power furnished. Responsible parties only need apply. Privilege reserved to reject any and all bids. For further particulars inquire of

CHAS. ALLENBERG, Sec'y.,
680 Brannan Street, San Francisco, Cal.

Improved Form of HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above cut of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "backing," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above. All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

JOSHUA HENDY MACHINE WORKS,
49 and 51 Fremont St., San Francisco, Cal.

THE CONSUMERS' COMPANY.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

MILL AND MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street. - - - San Francisco, Cal.

Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.

For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal. 145 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

SAWMILL MACHINERY,

Of all descriptions made to order.

SEND FOR CIRCULAR.

\$1,000 CHALLENGE!**THE FRUE ORE CONCENTRATOR,**

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Colombian Mines.

There are a number of places in the United States of Colombia where gravel mines exist, and the auriferous deposits are quite extensive. We had a conversation this week with Mr. Thomas H. Folingsby, who lately came from the State of Santander, U. S. of Colombia, and who is about to return to work on some gravel mines belonging to Mr. Joy, of Baranquilla. He says there is a wide belt of gravel extending along the range for some sixty miles. The banks average 200 feet, and there is plenty of water. He says they get about half a cent to the pan. The deposits were discovered in 1872, but have never been worked. The numerous creeks and gulches in the range were worked out by the Spaniards many years ago. All over the country ground sluicing has been carried on, and at each stream are relics of the old miners. The gravel banks were too poor to work, however, and they did not know anything about hydraulic mining. There is some mining carried on now by natives along the rivers, and the women dive for gold with their bateas at most of the streams where there are auriferous beds.

All the work done by the natives is done by ground sluicing or bateas, and with the latter implement they are very expert indeed. Labor is cheap, and some men by hiring 100 or more natives make money. In some parts of Canca, on the Pacific side, quite rich diggings are found.

On the other side, a number of English companies are doing good work, and shipping \$8,000,000 or \$9,000,000 a year from the mines. The English bring practical miners with them, and work for silver, gold, iron, etc., working underground mines. A number of Eastern companies have come down there, too, but most of them have lost a great deal of money. They bring outfits for working gravel and quartz, but have sent inexperienced men to look after their interests, and have not seemed to think it necessary to have any one with a knowledge of mines.

The mines belonging to Mr. Joy are being opened systematically. This gentleman is an Englishman, and quite enterprising, being the life of the region where he is. He is now building a railroad from Santa Martha to Baranquilla, 80 or 100 miles long. Appliances are to be purchased in this city to outfit the mines. There is no snow in the region for poor men, as it takes capital to equip the mines, and labor is nothing. There is an abundance of water and timber, and the climate is healthy.

NEW DISTRICTS.—The Walker Lake Bulletin of April 11th says: The Carson and Colorado railroad may almost be said to be making a country. As its track extends southward new districts come into notice, and old districts which have for years been known to be rich, but which were abandoned because the cost of transportation took away the profits arising from working the mines, again become prominent as certain bullion producers in the near future. Some of these districts, which will soon be ranked among the richest on the coast, have been nearly deserted for years, and were as though they had never been discovered. This was not because it was not known that great quantities of rich ore were to be found there, but because it was impossible to either extract or work it within the limits of reasonable cost, owing to the difficulty of carrying supplies.

Hydro-Carbon Blowpipe and Assay Furnace.

Assayers and chemists in the mining regions have for many years been using the same old form of assay furnace, but a new one has lately been devised and come into use, in which a hydro-carbon is utilized as fuel. A representation of the apparatus is given on this page. In the engraving, *P* is an ordinary force pump, at the bottom of which (at *A*), is a valve which

which such an apparatus may be put. The inventor recommends it to miners and assayers as a very convenient and safe apparatus for all furnace work, such as melting, scorifying, cupelling, fusions in platinum crucibles, (the blast being free from sulphur, etc., has no effect on platinum crucibles), testing of smelting charges, roasting, etc. Consumption of fuel is subject to so many conditions that absolute data can not be given; but in ordinary effective operations, it is stated a gallon will last about eight

ASSAYERS' PORTABLE MUFFLE FURNACE.

closes automatically upon releasing the pressure from the pump. *C* is a check valve which closes the inlet to the tank, *T*, completely. *F* is the filling screw. *H* is the pipe leading from the tank to the burner, *D*. *E* is the burner regulator terminating in a fine point, closing the orifice of the burner. *B* is the crucible furnace.

Upon pumping a few strokes, a pressure is

hours. Its action can be controlled from the heat of an ordinary Bunsen burner to that required to melt cast iron, etc. The maximum effect can be produced in about four or five minutes from the start.

Mr. Wm. Hoskins, the inventor and manufacturer, 81 South Clark street, Chicago, states that this apparatus will fuse assay charges, samples of smelting charges, scorify, cupel,

BLOWPIPE AND CRUCIBLE FURNACE FOR ASSAYERS AND MINERS.

created in the tank, which forces the fluid through the pipe, *H*, and the tubes of the burner, when it is vaporized by heating the burner, and finally issues from the fine orifice at the end of *E* as a highly heated gas, and burns as such with a powerful blast. After once being started, the heat of the flame passing through the burner vaporizes the fluid in the tubes, and hence it is automatic in its action. The air which is forced in is not used, and therefore it is only necessary to occasionally use the pump to maintain the pressure lessened by the consumption of the fluid, to keep up the blast. This apparatus is manufactured particularly with regard to portability, by a chemist and assayer who understands the various uses to

roast, etc., and will produce the highest heat without any dust or ashes, and without any exertion on the part of the operator. He says it will melt a half pound of cast iron in fifteen minutes with the furnace cold at starting, or ten minutes with the furnace hot; a pound of brass in eleven minutes with furnace cold at starting, and seven minutes with furnace hot.

As the question of cost of all such things is one of great importance to assayers and miners, we will take some figures from the circular, which gives an idea of expense. The crucible furnace weighs fifteen pounds, and takes crucibles from the smallest sizes up to five inches high by four inches at the top, and sells for \$4. This furnace takes Battersea U. or T. cruci-

cibles, or equivalent sizes of other makes, and can be used for cupelling or scorifying, but as only one or two cupellations can be carried on at once, a muffle furnace is made for the purpose. A second size furnace, eight inches by seven inches and nine and a half inches high, without legs, is heavier and better adapted for severe usage. It sells for \$5. The muffle furnace, which we illustrate, weighs twenty pounds, and takes a Battersea muffle five inches wide and seven inches long, costing, including nozzle, \$10, a smaller sized one being \$8. The blowpipe apparatus, complete, weighs seven and a half pounds, and costs \$18. A complete apparatus with No. 1 crucible furnace and No. 2 muffle furnace, packed ready to ship, weighs eighty pounds, and costs \$32. The blowpipe, complete, with No. 1 crucible furnace, costs \$22. Parts may be duplicated. Gasoline of 74° is recommended as the best fuel.

Diving for Gold.

There are a good many ways of mining for gold, and in California we have tried nearly all of them. In hydraulic, drift, placer, bench, bar, and river mining particularly, we are pretty well up. But we have never made a success of getting gold from the beds of rivers when the water was flowing over the bed. We have turned rivers aside and built wing-dams, etc., so as to get at the auriferous deposits, and have worked river beds at low stages of water, but none of our devices for pumping up gold from beneath the river have been successful or practical. Large amounts of money have been expended on dredges and pumps for working river bottoms and various plans have been adopted. In no case, however, has any money been made out of the operation. The failure of one did not deter another, until repeated failures were chronicled. And even now the same old plans are being tried elsewhere that have been abandoned here.

Still there are people who contrive to bring gold up from beneath flowing rivers and make money at it. Down in the State of Canca in the U. S. of Colombia, there are many deposits of auriferous gravel. Most of the small gulches and ravines have been worked out a hundred years ago, though more or less mining is still going on. Many large streams have auriferous beds and the natives are not up to turning the course of the river, so they mine in a peculiar way. The women take a batea in their hands and dive down in ten or fifteen feet of water, scrape the loose sand and gravel into it and bring it to the surface. Then they climb on the bank and "pan" it out. They get all the way from a few cents to four bits a batea. Sometimes the men engage in this work, but it is mainly done by the women. After a dive they set down on the bank and smoke a while before going down again. They teach the children of twelve to dive for gold also. Sometimes rich pockets or deposits are struck. Nobody but natives engage in this sort of work. At the Saragossa, the Clara creek, and the Tewee river a good deal of this mining by women diving is done.

Six Alaska mining companies publish their delinquent assessment lists, the whole making just thirty-one lines. The stockholders are nearly the same in each case. One of the certificates in the General Miller calls for 19,990 shares. Another certificate in another mine is for 13,522 shares, another for 12,322 shares, and still another for 10,495 shares.

CORRESPONDENCE.

Early History of the Comstock.—No. 4.

Sad Reminiscence—First Victim.

EDITORS PRESS:—Without contesting the priority of the first assays of the Comstock ore, allow me to state that it was in my laboratory, then located on Jackson street, above Montgomery, that, on the 28th day of July, 1859, I assisted Major R. Killalee in assaying some black silver ore he pretended to have received from Mexico, the Major at that time not having any smelting and cupelling furnace, occupying only a small desk in Joe French's office, opposite the old Metropolitan Theater. My acquaintance with the Major and Judge Walsh dated from 1854, during my sojourn in Nevada City. Joe French and myself were to have an interest in this mine if proved good, so with a will the black ore was soon pounded and fluxed. The smelting was all O. K., but the cupel buttons were stummers—over \$5,000 to the ton. The Major hardly would believe the results of these assays, although nobody was admitted that day in the laboratory. Again two new crucibles were used for another assay—cupellation nearly same results. The Major did not know what to say, but rather excitedly rapping the table with his cane remarked, "Well, Doc, let us try once more. *Toutes les bonnes choses sont trois.*" (Every one knows the Major could converse in German, French and Spanish languages fluently), and if the results are the same, then you and I will visit again La Belle France. Truly the results were the same. The Major was jubilant and very excited, but still very reticent about the location. It was about 6:30 when we left the laboratory, and we were to meet the next day at 2 p. m., but "man proposes, God disposes." Alas! the Major was found dead next morning, and at 2 p. m. it was my sad duty, as chemist to the Coroner at that time, to assist Dr. Nuttall at the post-mortem examination, which revealed the fact that the cause of death was the rupture of an aneurism of the arch of the aorta. Although, as Mr. A. Paul remarks, "some philosophers say information is wealth," in this case it was death; and thus my poor friend, R. C. Killalee, fell the first victim of Washoe excitement. It was only later in October that I learned the location of the ore from which we had made our assays.

San Francisco, April 11, 1883.

Fresno County Mines.

EDITORS PRESS:—Having just returned from a somewhat extended visit to a district but little known among mining men I will endeavor to give you some information concerning it, beginning with the Champion gold bearing lead, situated on Big Dry creek, Fresno county, Cal. The Champion lead is not a new discovery, but has been known to the ranchmen and shepherders for many years back, by which it is chiefly owned. And up to within a few months back nothing has been done toward the development of the lead except a few few prospect holes here and there, and the erection of a small four-stamp mill, run in a primitive manner by inexperienced hands.

It remained for Messrs. Anderson and Doak, the enterprising proprietors of the Carlwright mine, to develop to a certain extent the mineral richness of this lead. Their energy and push have enabled them to sink three prospect shafts on their ground, about 200 feet apart. In each of these they have followed the vein about 100 feet from the surface, at which depth the ore was of such quality as to warrant in running a tunnel to intersect the south shaft and to erect a ten-stamp mill on the ground.

They are now taking out about twenty-five tons of ore per day that mills from \$10 to \$14 per ton. The ore is contracted for, and is mined and delivered to the mill at a cost of \$1.65 per ton. The present contractors, Messrs. Ames and Downey, are experienced miners, and express themselves as highly pleased with the outlook in this section. The mill is a steam one, and there is ample water for amalgamating purposes.

The Champion vein is situated in the foothills of the Sierra Nevada, about twenty miles from Fresno City, Fresno county, and has been traced and opened nearly one and one half miles in length. The pay vein varies from two to nine feet in thickness, and I have no doubt that ere long this district will rank among the first in the State.

In my next I will mention other mines in this vicinity, including some splendid copper prospects.

ALBERT P. GABBS.

Gertrude, Fresno county.

FORMATION OF THE SOLAR SYSTEM.—At a recent meeting of the London Physical Society, Mr. Braham gave an experimental demonstration of the vortical theory of the formation of the solar system by rotating a drop of castor oil and chloroform in water until it threw off other drops as planets.

Coal for Arizona.

Now that some of the Arizona mills have already commenced to order coal for future use, in place of the familiar cedar so long in use, a few items concerning the source from which the future supply is to come from may not be amiss. The nearest coal mines to this county are at Gallup, on the line of the Atlantic & Pacific railroad, and some 150 miles west of Albuquerque. The A. & P. railroad obtains nearly all of its coal from the mines at Gallup, and, in fact, uses the larger portion of that produced. The following description of the coal mines, taken from a recent number of the *Albuquerque Democrat* will prove interesting:

The Gallup Coal Mines.

There are at present three prominent producers here. The most important and well developed one is the group of mines owned by Messrs. Pegram, McMillan, Lackey and Weaver. It is situated some two and a half miles from town, on a low foothill formed by an upheaval of vast sandstone layers. There are four distinct veins of coal here, being respectively of a thickness of six feet, five feet ten inches, four feet eight inches, and four feet. These veins lie from twelve to twenty feet apart from each other and are nearly horizontal. The coal is drawn by mules to the surface. The daily average shipment is about 225 tons, which can however be increased at once to much larger proportions. The produce is shipped all along the line as far as Albuquerque, although the Atlantic & Pacific road uses so far the larger portion of it. It is sold for \$2.90 a ton delivered at the cars, and \$3 at retail. There are extensive

Surface Improvements

At this mine, consisting of boarding-houses, stables for the numerous animals, offices, and a substantial chute holding over 200 tons, etc. There are from 80 to 90 men employed, and 26 teams are running all the time, working over 100 animals. A big boarding-house is kept for the accommodation of the employees.

The next producing mine is that of Messrs. M. Bell & Co., about a mile west of town. Here some 25 men are employed, who take out from 50 to 55 tons daily. The vein which is struck at a depth of over 190 feet, is over 6 feet thick, and pitches into the hill at an angle of 35 degrees. The coal is hoisted with a whim, worked by two mules. It is a superior article of lignite, and leaves on burning no clinkers, and only a small percentage of fine red ash.

The remaining producer is Patton's mine, some three miles below Gallup, which ships from sixty to seventy tons a day. There is also, some eight miles distant, at Defiance, Tucker & Talbot's mine, which makes regular and certainly increasing shipments.

Character of the Coal

The product of all these mines is of a bituminous character, but it is very hard and compact, and would, by many a superficial observer, readily be classed as anthracite. In fact, as great depth is obtained, it would not be at all astonishing if veins of regular anthracite should be discovered. It is not a coking coal; there is, as far as heard from, none of that kind in the Territory. But for steam purposes, it is excellent, and for railroad use it can not be surpassed. In one or two of the veins that are at present worked here, there are thin seams of slaty stone running through the coal. They are called "bones," and while they do not interfere with the character of the coal itself, they are somewhat troublesome to the miner, and keep him from getting ahead with his work as rapidly as he could wish. The formation of the low hills which surround the plain in which Gallup is situated is sandstone of various colors, red, brown and gray. The coal veins are usually under and overlaid by thin layers of slate, and occasionally by layers of limestone.

With coal delivered on the cars at Gallup at \$2.90 per ton, we certainly ought to get it laid down at Hackberry or Wallapai siding at \$10 per ton, and we expect to see coal laid down in Mineral Park for about \$17.50 per ton, or perhaps less. At this price it will be much cheaper than wood at \$10 per cord, and will probably supersede it entirely.

Good News for Miners.

We had the pleasure of meeting C. L. Hubbs, the manager of the Gran Quivira Mining and Smelting company, of Albuquerque, New Mexico, during the past week. He has been visiting most of the prominent mines in this and surrounding camps with a view of seeing for himself how much ore there is in this district and acquainting himself with the different grades and qualities which are produced here. He expresses himself wonderfully surprised at the number and size of our ledges, and the richness of the ores they contain, and more especially is he surprised at the amount of ore lying on the dumps of the different mines. He proposes to give the miners such good rates for ore that it will pay every one of them to sort over their dumps and ship the ore that heretofore has been considered worthless. He offers the following prices for ore: Gold, \$18 per ounce; silver, \$1 per ounce; copper, \$1.50 per unit; from 20 per cent. to 30 per cent. lead, 30 cents per unit; from 31 to 40 per cent. lead, 40 cents per unit, and from 41 per cent. upwards, forty-five cents per unit. He charges \$20 per ton for working, and makes no charge for crushing, sampling or assaying in lots of one ton or over, and deducts no discount

or percentages. He has secured terms from the A. & P. railroad, which will allow miners here to ship ore by the carload to his works at Albuquerque for the low price of \$8.50 per ton. At these figures, \$50 ore will net the miner \$21.50 per ton delivered at the railroad, and at these rates there should not be an idle man in the district. To obtain these rates, ore must be shipped in carload lots, but it is not necessary that a carload should be made up from one mine, and three or four or more may join together and make up a carload between them. The ore may be shipped direct to the works or consigned to the Central bank, which will see to the sampling of it and collect and return the money for it. If this does not satisfy the miners of this county, then indeed we shall think they are either hard to please or else too lazy to work.—*Mohave Co. Miner.*

SILK HANDKERCHIEFS AND SORE THROATS.

Sore throats vanish when encircled in a silken kerchief. This is established beyond peradventure. The grandmothers knew all about this a hundred years ago. They believed, too, that silk would cure all other diseases, and some of them thought it would heal a broken leg "if only taken in time." We do not go so far as that, but we know that silk will absorb and store electricity as readily as a Leyden jar. It forms an essential curtain for the electric cylinder, and rubbed with quicksilver, has a mysterious power that imparts force to its retention. The curative force of silk is due to its electricity, and the medical faculty recommend silken hose and shirts for a thousand diseases. As we are not professional, we only take silk by the throat, and know its wonderful powers. We will give a sure recipe: When you have the throat trouble, give a nice, clean silk handkerchief to your sweetheart with a request to tie it around your neck. If you are not cured or choked by tender hands we have made a mistake. The more expensive the kerchief the surer the cure, because your pet takes so long to examine the quality and get it just right, so it won't hurt. Try it and go home cured. We expect silk handkerchiefs will advance in price, when this matter is understood.—*Dry Goods Bulletin.*

PRIZE FOR AN IMPROVED SAFETY LAMP.—Ellis Lever has offered a prize of \$2,500 for a perfect safety mining lamp. The conditions are now before us, and we heartily trust that the deposited award will never revert to the philanthropic donor. The money has been deposited with the Central Board of the Miners' National Union, to be, pending the award, vested in three trustees. The lamp must be perfectly portable, electric or other lamp, which the miner can carry from place, and which will not under any circumstances whatever cause an explosion of gas. The lamp must be submitted to the judgment of five gentlemen, impartially chosen, who are best qualified to decide, and the offer will remain open to the close of the present year. If the "perfect lamp" is not produced, Mr. Lever will have the money returned to him.—*Mechanical World.*

MICA PRISMS.—At a recent meeting of the Physical Society, Mr. Lewis Wright read a paper on the "Optical Combinations of Crystalline Films," and illustrated it by experiments. He exhibited the beautiful effects of polarization of light, and the Newtonian retardation by means of plates built up of thin mica films and Canada balsam. The wedges thus formed gave effects superior to those of the more expensive selenite and calcite crystals. The original use of such plates is due to Mr. Fox, but Mr. Wright showed many interesting varieties of them, including what he termed his "optical chromotrope," formed by superposing a concave and one fourth wave plate on each other. Norenberg's combined mica and selenite plates were also shown.

AN OLD STORAGE BATTERY PATENT.—Electricians are interested at present in the discovery, in the Patent Office of a patent issued February 6, 1861, to C. Kirchhoff, a New Yorker, for an electric battery which presents all the features of the storage batteries in use at the present day—lead plates immersed in acidulated water, which becomes coated with the oxide of lead. The principle appears to be the same as that of the Plante (French) storage battery, and the storage batteries now in market must hereafter rely upon peculiarities of construction instead of comprehensive claims.

Indian Question.

The Indian question is up again. The terrible Apaches are on the war-path, in paint and feather, murdering men, women and children, and desolating the country, merely to appease a brutal appetite for robbery and blood. The Government troops, as usual, are galloping over the country trying to drive these savages back upon the reservations. The Arizona editors, wearied out of patience by these frequent outbreaks, think the time has come to exterminate the savage tribes, and the San Francisco *Examiner* winks approval. This gives the *Argonaut* a spasm of sentiment; it says the Indian usually goes upon the war-path to seek revenge for the cruel wrongs he has received, and advises the Arizona editors to kill off

the gamblers and cowboys before they wildly scream over the offenses of the desperate red men.

At every Indian outbreak the question comes up, what shall be done with the hostile savages? and remains unanswered, and seems likely to remain so for some time yet. The aim of the law, both in its enactments and execution, is to protect the good element of society from the encroachments of the bad, and supplant the bad with something better. To know how to segregate the good from the evil, and promote the growth of one and discourage the growth of the other, is the first step in all wise legislation. Is civilization, then, better than barbarism? This is the first question that meets us in discussing Indian affairs. Of course we must assume the affirmative, for were the converse of the proposition true or even doubtful, then the most stupendous blunder and outrage has been perpetrated by building a nation of fifty millions upon the hunting grounds and fishing privileges of a few hundred thousand savages. Were we to take the narrowest view of civilization and the highest view of the savage state, it would still be clearly apparent that the latter must give way. The law must protect the best. Destiny has decreed it. And in the race of life the best wins, and the weak and inferior must go to the wall. Hence, in determining what to do with the savages, the policy of the Government should be decidedly in the interest of civilization. The life of one settler on the frontier is worth more than a tribe of these barbarous marauders and murderers. And yet the Government has strangely and uniformly pursued a course that has tended to preserve the savage condition of the aborigines. Whenever the interests of civilization and barbarism have come in conflict the sympathy of the majority remote from the field of bloodshed and atrocity has come to the support of the savage. A mawkish literature embalmed him as a martyr. Poetry and song wailed his woes. The coarse, brutal, treacherous savage chief, whose wigwam dangled with the scalps of white men, found himself a hero at Washington, and well received by the authorities. No doubt the Indian has often been the victim of wrong, but the kind of sympathy we find lavishly expended in such works as "A Century of Dishonor" and in the speeches of Boston philanthropists, is of that soft-hearted, flabby, puerile sort, that sends bouquets and dessert to atrocious murderers, and coddles and apologizes for a polygamous reprobate.

The recognition of these savage, nomadic tribes as sovereign powers to be treated with in a diplomatic way, has been the leading error of our governmental policy. The treaty-making power is one of the highest acts of nationality. With the Indians it is a huge farce. Think of a Commission of disguised Ambassadors of a great nation on one side, and a few savage chiefs, dirty, lousy, lazy, repulsive creatures, meeting on the same plane to negotiate a treaty! The whole scene is supremely ridiculous, and only tends to pamper the self-importance of the chiefs strengthen tribal relations, and destroy every sense of gratitude and responsibility to the Government.

Then our present system of reservations, corralling a lot of "bucks" and squaws upon a small slice of territory, has proven a miserable failure. It amounts to but little more than training and fattening the restless Indians during the winter, for the war-path in the spring, and the more peacefully inclined become lazy, shiftless, dissipated and worthless. Judge Henry C. Dibble, a leading citizen of Arizona, in his open letter to the President, points out in a forcible way the folly and wickedness of quartering savage tribes in the midst, or in the vicinity of civilized communities, and unless the policy of the Government soon becomes more vigorous and effective, we could hardly blame the citizens of Arizona for promptly settling this question as the citizens of Minnesota did a few years ago.

MECHANICAL PROGRESS.

Explosions Made by the Squeezer.

Persons who have no knowledge of iron rolling mills have often been surprised on passing them by numerous cannon-like explosions within. These explosions are the cause of much conjecture, and for the benefit of those who do not yet understand how they are produced, I will attempt an explanation of them. Before I proceed with my explanation, however, it will be necessary to briefly describe the process of making, for example, merchant iron.

The puddling process is the conversion of cast or crude iron into wrought iron, and the puddler and the puddling furnace are the instruments employed to effect the change. After the iron has been prepared in the puddling furnaces, it is taken out very hot in balls weighing from 175 to 200 pounds, and thrust into a machine called a squeezer, which carries the ball around until it (the ball) has described a horizontal circle, and then ejects it, the ball emerging from the machine in the shape of a sugar loaf. The ball is now called a puddled bloom. It is next taken to the puddle rolls, and rolled into a bar of any dimensions required. The next thing done in the process of manufacture is to cut the bars into pieces to make piles of weights desired, and then roll the iron into merchant iron.

The explosions occur while the iron is passing through the squeezer, and are caused by running water on the machine to keep its heat down, and thereby prevent unequal expansion. During the passage of the metal through the machine the compression is so great that the fluid sinder is expelled from the metal, and the water coming in contact with it creates a gas which explodes with a loud report. These explosions can be avoided by running the squeezer dry, but, for reasons above stated, water is run on the machine while in operation.

The Working of Soft Steel.

Mr. Barnaby, Admiralty Inspector at Sheffield, has made a series of very interesting experiments, with the object of determining the influence of heat upon the strength of iron and steel. The test pieces of open-hearth Bessemer steel and iron were furnished by C. Cammel & Co., and by John Brown & Co., and Mr. Barnaby describes very fully the results obtained and the means employed to secure specific temperature.

Mr. Barnaby insists that the results obtained are such as to dissipate all doubt as to the practicability of using soft steel in boilers, and under all circumstances where it may be exposed to high temperatures. Very thorough experiments seem to have established the fact that Bessemer steel heated to about 400° F., increased its tensile strength ten tons per square inch, while the elongation diminished only one thirtieth; high temperatures do not seem to augment the tensile resistance of open-hearth cast steel in the same degree, while the elongation is about equally diminished. This increase in strength and diminution in elongation continue up to about 600° F. Tests at still higher temperatures are wanting, yet at 880° F., the elongations were found to be in excess of the requirements of the Admiralty.

Mr. Barnaby has also carried on experiments with a view to determine the required treatment of pieces which had been subjected to punching, shearing and upsetting, in order to counteract the effects produced by these manipulations. The total results of his experiments show that the working of steel offers no more uncertainties than that of iron, if the precaution is taken to heat the piece, after working it to a cherry-red and then dip it either into boiling water or into oil. Immediately after this mild tempering, and just as soon as the piece has acquired either the temperature of the water or the oil, it may be put into the structure. Mr. Barnaby concluded from his experiments, that this form of tempering completely eradicates the effects of shearing and punching.

A NEW ELEVATOR BRAKE.—Edwin C. Post, of Toledo, Ohio, has constructed a new style of elevator which has passed a severe test successfully. Its peculiar advantage over others is that the air is compelled to act as a brake, giving a yielding force and stopping the car quickly but gradually. The test consisted in putting on much more weight than its given capacity, raising it to the top of the building, then severing the supporting cables. The car with its heavy load, unsupported, dropped only six feet, when it stopped gradually in a descent of four or five feet, and remained stationary. The cables were again attached and other tests given, the car making fast or slow ascents and descents as desired.

A NEW TOOL.—A convenient little tool has just been patented in Germany for boring a hole through an opening much smaller in diameter than the hole itself. The tool consists of a shank in which small knives are concealed; the shank is inserted into the hole, a spring at the end is pressed, and the knives spring out of the shank to the required distance. They are, of course, curved and shaped so that they work together on the same principle as an auger.

INDURATED WARE.—The manufacture of indurated ware is a new industry, and Portland claims to own the only works of the kind in existence, the factory of the concern being located near Waterville. The articles manufactured are washbowls and pails, though lamps have been made, and attempts are being made to manufacture spool heads, and various other articles. The material used is wood pulp, made from spruce at a manufactory in Boston, and the same as used for the manufacture of paper. The ware is thus practically paper ware, as the pulp is treated the same as though it was to be made into paper; though at this point everything changes. The pulp, instead of passing through the rollers of a paper machine, flows into a mold capable of exerting a pressure of 3,500 pounds, and in three minutes the jaw of the mold drops and a washbowl or a water pail drops out. When thoroughly dried in the atmosphere the bowl or pail is passed into a machine fitted with the proper forms and subject to a pressure of 500 tons, from which it emerges with a shape that cannot be changed. Though comparatively smooth, the articles are next sandpapered on a machine making 1,200 revolutions per minute, and then treated with a chemical preparation that outwardly changes them into a substance resembling horn, and in which condition they may be immersed in boiling water for hours without change.

SAW MANUFACTURE IN PARIS.—Some of the Paris saw manufacturers have introduced some improved processes of treating both the teeth and the blades, the latter after being rolled cold several times, in order to render the grain close and the metal homogeneous, are heated in special furnaces, from which the air is carefully excluded, and which at a proper temperature are plunged into a bath of colza oil, this being done in a dark chamber. The tempering is effected with the aid of machines, which cause the blades to pass between cast iron plates, heated to a fixed temperature, according to the quality of the article to be produced. The teeth of the saws are cut out by machinery, which requires only laborers to attend it; the planishing and grinding of circular and other saws are also accomplished by machinery with great advantages on the score of regularity and stiffness. Another feature to be noted is the mechanical reduction of the joints of ribbon saws by grinding instead of filing, this being done longitudinally instead of across the blade, thus securing perfectly uniform thickness.

STEEL FORGING.—At a recent meeting of the Newcastle-on-Tyne Chemical Society, a paper was read on the "Variation in the Composition of Steel Forgings," which gave the results of a series of analyses made to ascertain if there was any difference in chemical composition between the central parts and the surrounding material of steel forgings. Samples of metal were taken from a forging of seven and three fourths inches in diameter, and formed from an ingot three tons in weight. These were submitted to analysis in the laboratory, great care being taken to obtain comparative results. The tests showed that impure metal was contained within a radius of one and one half inches from the center. The general conclusion from numerous other experiments, is that those parts of a steel forging corresponding to the part near the top and bottom ends of an ingot are homogeneous in their composition, and those parts of the forging corresponding to the middle of the ingot contain a core of accumulation depending upon the size of ingot and the rate at which it cools.

EXPANSION AND CONTRACTION OF IRON WIRE. Some of the anomalies presented in the expansion and contraction of iron wire, as observed by metallurgists and chemists, have led to the conclusion, recently, that in steel and iron containing free carbon, there is a contraction or shortening which is excited by heat, and which proceeds simultaneously with the dynamical expansion and marks its true amount—this being divisible into high and low temperature contraction. In cooling a strained iron wire from redness, it was found that the contraction due to cooling was, at a certain point and for a limited period, changed into action of elongation; in good iron wire this irregularity has not been detected, but in hard wire and steel is very apparent. The wire has to be raised to a very high temperature before the temporary elongation during cooling is visible, nor does it take place if the wire is heated only just beyond the temperature at which it occurs.

A NEW METHOD OF MANUFACTURING BELTS or bands for machinery, which comes from Paris, is applicable to rubber, woven tissues of gutta-percha, and consists in making the belt in longitudinal ribs or grooves, the main object of which is to increase the capacity of the belt on the same cross section, say twelve inches, by the extra strength put in the same space, and also to prevent so much stretching and variation. Another modification of the same invention is grooving one side of the belt the same as saw teeth, then putting these two pieces together, leaving a plain bearing surface for contact besides, thus making a double belt, which is less liable to stretch or to warp. Especial machinery is built for the purpose, and the claim for it is that better contact is given. The pores are closed during this grooving process, the belts have a higher resisting power, and do not twist on the pulleys. The grooves may be regular, irregular, spiral, or crossed.

SCIENTIFIC PROGRESS.

Influence of Metals on the Oxidation of Oils.

Metals have in certain cases been found to exert a remarkable influence on the oxidation of oils. Quite recently M. Livache, of Paris, used in this relation finely divided metal, such as is obtained by precipitation, instead of metallic plates, and the effect was found to be greatly increased. He thus tried lead, copper and tin, and found lead to have the strongest action. If lead moistened in oil be exposed in air, an increase in weight is very soon observed, and this is greater the more siccative the oil. With linseed oil the increase of weight reaches a maximum in thirty-six hours, whereas, exposed alone to air, the oil would take a much longer time to reach this maximum. A solid and elastic product is obtained. With non-drying oils the increase of weight is much less, and takes much longer to be completed. The result in question, M. Livache points out, cannot be attributed to a simple division of the matter, allowing more active circulation of air, for the same experiment made with various other substances in fine division does not result in any like increase of weight; the effect is merely like that in the case of a thin layer of oil exposed to air. The change in the other case must be attributed to a direct action of the metal. Operating with different oils, M. Livache found the increments of weight proportional, except in the case of cottonseed oil, to those observed in the fatty acids of the oil exposed to the air for several months. He suggests that industry may derive certain advantages from the facts observed. Thus a rapid method is indicated of distinguishing drying from non-drying oils. Further, the heating of oils might be advantageously replaced by a circulation, in contact with air and in the cold state, over iron or fine plates having precipitated metallic lead on their surface. The oils so obtained would be always less colored, and would retain great fluidity, while the objectionable odors and the danger of fire which attend the present mode of treatment would be avoided.

Theory of Magnetism.

In the year 1879, Prof. D. E. Hughes, F. R. S., communicated to the Royal Society of London, a paper "On an Induction Currents Balance and Experimental Researches made therewith." He continued his researches into the molecular construction of metallic bodies, and communicated the results then obtained in three separate papers bearing upon molecular magnetism.

From numerous researches in this direction he gradually formed a theory of magnetism entirely based upon experimental results, which led him to the following conclusions:

1. That each molecule of a piece of iron, steel, or other magnetic metal, is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism when noticed upon a steel bar magnet.
2. That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress, or by physical forces, such as magnetism and electricity.
3. That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can neither be augmented nor destroyed.
4. That when we have external neutrality, or no apparent magnetism, the molecules, or their polarities, arrange themselves so as to satisfy their mutual attraction by the shortest path, and thus form a complete closed circuit of attraction.
5. That when magnetism becomes evident, the molecules, or their polarities, have all rotated symmetrically in a given direction, producing a north pole if rotated in this direction, as regards the piece of steel, or a south pole if rotated in the opposite direction. Also, that in evident magnetism, we have a still a symmetrical arrangement, but one whose circles of attraction are not completed except through an external armature joining both poles.

THE SENSE OF DIRECTION IN ANIMALS.—The remarkable faculty which cats, dogs, pigeons, and other animals possess, of returning in a straight line to a point of departure, has awakened much curiosity on the part of naturalists. Some refer it to instinct, some to intelligence similar to that of man, some to an internal mechanism which makes the animals simple automata; but none of these attempted explanations do anything towards solving the mystery. Wallace supposed that when an animal is carried to a great distance in a basket, its fright makes it very attentive to the different odors which it encounters upon the way, and that the return of these odors, in inverse order, furnishes the needful guide. Toussend supposes that birds recognize the north as the cold quarter, the south as the warm, the east (in France) as the dry, the west as the moist. Viguer, in the *Revue Philosophique*, publishes an original memoir upon the sense of orientation and its organs, in which he attributes the faculty to a perception of magnetic currents.

Constitution of the Sun.

In a paper recently presented to the French Academy, Faye gives his reasons for believing that our sun and the other large self-luminous heavenly bodies have not yet arrived at either a solid or a liquid state, but are gaseous all the way to the centers. Otherwise, he says, the heat radiated from them would not be so quickly replaced by heat from within, and the surface, consequently, would soon become covered with a solid, non-luminous crust.

Cagniard-Latour has proved by means of some very remarkable experiments that a gaseous mass can acquire the density of a liquid without changing its state of aggregation, provided both temperature and pressure are high enough at one time. If, then, the external strata of the solar atmosphere, where all matter is in an elementary or dissociated state, should cool sufficiently for the elements to enter into chemical combination, if the vapors of metallic calcium, magnesium, and silicon, mixed with oxygen there, on cooling should form clouds of lime, magnesia, and silica, for example, these clouds would sink to the interior, where they would again be dissociated, while at the same time they would drive the hotter particles upward, so that an approximately uniform temperature would be maintained until the whole mass had gradually cooled to such an extent as to assume the liquid and afterwards the solid state.

Faye bases his hypothesis on the spectroscopic observations of many years, and on Carrington's study of sun spots, which show that the currents are all in zones parallel to the equator, while there are none from the equator toward the pole. Besides this, the flattening of the sun and the slow motion of the sun spots near the poles are more easily explained on this hypothesis of Faye than on those hitherto in vogue.

A NEW SECONDARY BATTERY.—Secondary batteries are now rapidly multiplying in number, and among recent inventions in that direction we would mention a new form of battery proposed by Messrs. Liardet and Donnithorne, of London, England. The main features of the appliance, as stated by the inventors, are the intermixture of porous lead, deposited either by direct action by means of a galvanic current, or by the action of spelter with oxides and salts of lead, such as may be produced from galena or other lead ore, as the acting substance of the plates, to accumulate the current. This mixture is placed on very thin plates of pure lead, which serve as conductors, and is kept in position by porous plates. Great stress is laid upon the purity of the lead and lead compounds, as by this means the inventors seek to avoid local action and to increase the intensity and durability of the battery. An experimental set of cells recently tested consisted of fifty elements, each of which had an area of one twelfth of a square foot, the weight of the set being 315 pounds. The cells, having been charged with a dynamo, are reported to have given a current of twelve amperes with an electro motive force of ninety-five volts. The inventors claim that they have produced a secondary battery or accumulator of half the weight, half the cost and nearly twice the power of any other.

GOD IN NATURE.—In a recent scientific lecture, Prof. C. A. Young, the astronomer, of Princeton College, used the following language: "Do not understand me at all, as saying that there is no mystery about the planets' motion. There is just the one single mystery—gravitation—and it is a very profound one. How it is that an atom of matter can attract another atom, no matter how great the disturbance, no matter what intervening substance there may be; how it will act upon it, or at least behave as if it acted upon it, I do not know, I cannot tell. Whether they are pushed together by means of an intervening ether, or what is the action, I cannot understand. It stands with me along with the fact that when I will that my arm shall rise, it rises. It is inscrutable. All the explanations that have been given of it seem to me merely to darken counsel with words and no understanding. They do not remove the difficulty at all. If I were to say what I really believe, it would be that the motions of the spheres of the material universe stand in some such relation to Him in whom all things exist, the ever-present and omnipotent God, as the motions of my body do to my will—I do not know how, and never expect to know."

ORIGIN OF THUNDER-STORMS.—Spring attributes the appearance of a thunder-storm to a sudden condensation of atmospheric vapor, not into a mist but into hail. The source of the electricity is the rupture of the adherence of the air to the particles of hail; the electric influence then carries the electricity, which was accumulated upon each particle of ice, to the particles which form the limit of the frozen region. Abbe Moigno fears that this theory rests on a vicious circle, for the condensation of water, under the form of hail or rain, can only take place by reason of an electric discharge. All the secret of thunder-storms is to be found in a nimbus encountered by a very cold, very dry and highly electrified cirrus.—*Les Mondes*.

LEAF WORK.—It appears that the leaf of a plant can transform into useful work as much as forty per cent of the solar energy it receives and absorbs.

MINING SHAREHOLDERS' DIRECTORY.

Mining Share Market

There is little of interest to refer to in the share market at present. Our tables show all the fluctuations on the Comstock.

At the north end, prospecting operations are going on at several points, but as yet no developments worthy of special mention have been made. Frequent seams and streaks of quartz have been cut that give low assays, and some from which samples that would assay high might be taken, but these being mere feeders, it would be injudicious to make any excitement about them, for, after each little rally, there would be sure to be a relapse, and more harm than good would be done. Just as soon as anything likely to be of permanent value is found in any one of the north end mines, the public will be allowed to see and judge for themselves.

At the middle mines some very interesting explorations are now being made. The Hale and Norcross folks are thoroughly exploring to the southward the streaks of quartz cut by the north drift on the 2600 level, near the east wall, and are finding ore that will pay well for milling, though as yet the deposit is of no great width. In going further south, or upward or downward, these streaks are likely to bulge out and form a valuable workable deposit. It also remains to follow the ore streaks to the northward. No one can tell in what direction a deposit of ore may lie. All that can be done is to hunt for it.

At Gold Hill the leading mining companies are extracting much low grade ore from the old upper levels, all of which is milled and pays a small profit.

Mc CARTHY'S ANNUAL STATISTICIAN.—This valuable and unique publication has just reached its seventh annual volume. It is the only publication which comes anywhere near being an *omnium gatherum* of all really useful statistical information, and its importance and usefulness has been recognized everywhere that the English language is spoken, and, to a large extent, wherever civilization extends. It has been universally approved by all educational institutions and authorities to whose attention it has been brought. The present volume is as full of interest as ever, and, if possible, more valuable than any preceding edition. It contains 624 pages crowded with important facts, statistics and useful information. Published by L. P. McCarthy, 706 California street, San Francisco. Price, \$4.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

The receipts of bullion in New York city from the mines in 1882 is given at \$21,793,298.38.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

SUTTER CREEK.—Cor. Amador Ledger: At the Mahoney the machinery of both mine and mill is again in motion. Timbers, cordwood, wedges, etc., are being taken out of the drift in large quantities, and what they were sent down for is a mystery. But few men are employed at present, but the number is being increased almost daily, warranting the belief that before many weeks have passed the force will come up to its old standard. Ten stamps of the mill were started yesterday morning. They are running on rock taken principally from an open cut near the mill. It is estimated to yield at least \$6 per ton, and, as the expense of getting it to the mill will be trifling, the prospects of a remunerative run are flattering. Repairing the shaft of the Amador mine is progressing slowly. It is a difficult job, and will require a month more to complete it, and enable sinking to be prosecuted. Thirty stamps of the mill are running on quartz from an open cut near the shaft, which is said to be of fair quality.

MISCELLANEOUS.—The Kelly mill has completed the crushing of rock from the Vaughn mine, which joins the Kelley on the east. The clean-up has not been finished as yet, but we are informed that everything indicates a satisfactory yield. W. F. Walton has made arrangements with James Morgan to crush, at the Kelly mill, 5,000 tons of ore from the latter's claim near by. It will take three months to run through this quantity. The Oneida gravel claim is being vigorously worked; two parties with sluice boxes, and a giant playing on the auriferous dirt. W. E. Stewart has purchased the four-stamp battery of the old Kearsling mill in Jackson. He is removing the same to a quartz claim a quarter of a mile north of Big Bar bridge. He has a ledge from 3 to 6 ft wide, which he expects to yield \$5 per ton.

PLYMOUTH NOTES.—Cor. Amador Dispatch, Apr. 14: We have been looking at the mines in this part of the county in the last few days, and are satisfied that the best mines in Amador county are the Empire and Pacific mines, at Plymouth. There is more activity about these mines, and there is no doubt that they pay better than any other, (the Keystone not excepted,) and there is an abundance of the same kind of quartz ledges that can be had cheap for cash, that will certainly pay just as well if the parties working the same would do like Hayward and go down 1300 or 1400 feet. That seems to be the secret of success in these mines, and Mr. Hayward, having experience, goes after them in the right style every time, and is always a successful miner, never to our knowledge having made a failure. The Amador Pacific mine of this place is, beyond a doubt, the richest mine in the county, and very likely the richest mine in the State, and very extensive, and will last for years to come. It is only a few days ago that we were informed that a body of ore about 20 feet wide had been struck in the Pacific that would pay \$20 to the ton, that was running directly into the Empire mine works, and is supposed to be a new body of rock not known before. This will be sure to give the Empire a new impetus, as the ore taken from the Empire has been of low grade. The Pacific mill is a fine structure running 40 ten-hundred pound stamps, and containing concentrators of the most approved pattern. The mill is run by water obtained from the Amador Canal Co., at a very heavy expense, but is considered much cheaper than steam. The Empire mill is an 80-stamp mill, also run by water, and capable of doing as much work as any mill of the same size in the State. The whole business is under the management of Mr. Montgomery, General Superintendent for Hayward, Hobart & Co. The Vatican mine is on a range about one mile west of the Empire and Pacific ledge, on what is known as the old Ocher lead, and the same range extends into El Dorado county, and is known as the Spring Hill range in El Dorado county. There are several companies besides the Vatican Co. working on this lead, and are all making good wages. There is sure to be more interest taken in the mines that are in and around this place, as there are richer deposits here than in many places where large sums are squandered annually. Some people hint that the mines hereabouts would have been developed long ago but for the interference of some very highly interested parties that want to grasp the entire mining interest of Amador county.

BUTTE.

A DEMAND FOR MINES.—Butte Record: Judge L. C. Granger, of Oroville, who was a prominent member of the late Assembly of California, arrived in Chico last evening. The judge said that he was on a tour of inspection of the Butte creek mines, he having been sent out by San Francisco and Eastern capitalists. The judge said that there is a greedy demand for hydraulic mines where the debris can be impounded or deposited where it will not injure adjoining property. Little interest is being taken in quartz mining of late, capitalists not caring to risk a fortune in a mountain of rocks, even though good mineral does crop out. The judge informed a Record reporter that there is a renewed activity in mining all along Feather river, and one is reminded of the old days, when the river was worked with windmills, flumes or rockers. Claims are daily being taken up along that stream, and worked with good results. Old Butte county is still running over with gold, and it is not very hard to get at, either. Mr. Granger said that W. H. Farley, of Concord, was in Oroville yesterday, and employed 40 men to work in the Duensing claim, on the North Fork of Feather river, above the Big Bend tunnel. This claim has been panning out big results. Its owners will windmill the river. The Big Bend tunnel, the greatest mining experiment ever undertaken in the State, is now in over a distance of 1,000 ft. When completed it will be two miles and a half long.

CALAVERAS.

ROYAL.—Mountain Echo, April 14: J. F. Curtis, who some months ago sold a quartz mine in Salt Spring valley, has recently purchased another called the Royal mine, which is situated in the same district. He states that the ore from this mine yields from \$10 to \$18 per ton. Twenty tons of the ore has lately been shipped to New York for the purpose of thoroughly testing the mine.

REPAIRING MILL.—Calaveras Chronicle: The gravel mill on the Rough Diamond mine, in Chili gulch, has been stopped for repairs. A cam was broken some two weeks ago. A new cam was obtained, but, when about to put the cam in place, it was found that one end of the cam shaft was cracked for a considerable distance. As the shaft was originally intended for ten

gaged during the winter sinking shafts at various points and otherwise prospecting the company's ground, by which means it has been ascertained that over 200 acres of the ground is good, with an area 3,000x1,500 ft in extent, and most conveniently situated for washing, that is very rich.

GRIZZLY.—About a month ago work was resumed in the tunnel of the Grizzly mine, situated just above town and on the south side of Mill creek canyon. The tunnel is now in about 120 ft, and is being steadily pushed along the footwall of the vein, which is a large one. Some fine ore has been encountered in the line of the tunnel.

MONO RATTLENAKE.—Harry M. Hartley and Horace Warner are making preparations for sinking a joint incline shaft on a small but very rich quartz vein traversing what was the richest placers of the Old Mono diggings.

MAY LUNDY.—Supt. Kellogg arrived Thursday, and on Friday placed 30 odd men on the road between the mine and mill to shovel out the road for the quartz teams, which are expected here to-morrow or next day. The heavy snow storm of two weeks ago caused an avalanche, which damaged about 180 ft of tramway.

JAW-BONE MINING MATTERS.—The few men at Mount Gibbs are supposed to be still at work, though the regular monthly pay day has again been passed—for the sixth and all preceding months. The great "Ontario Syndicate tunnel," started in this district under the same jaw-bone development auspices, was closed more than a month ago, because the miners working there concluded that one whole winter was long enough for them to work for a speculator without means.

IS BIER.—Work on the Great Sierra tunnel, Tioga, is progressing as usual. The Mono Lake Hydraulic M. Co. has a good supply of water, and is pushing work accordingly. The mill of the Summers Con., Sweetwater, has been increased to 15 tons capacity, and is turning out an increased quantity of bullion. Ore is being taken from the winze, 30 ft below the main level and 370 ft below the surface, and the mine is showing well.

NEVADA.

MORE SLICKENS.—North San Juan Times, April 14: A blast of 13½ tons of Judson powder—about 500 cases—was let off at the American mine on Thursday evening last. This will supply the valley people with slickens for some time.

STRUCK A STRINGER.—*Foothill Tidings*, April 14: Besides the copper mining in and around Spenceville there is considerable prospecting going on for gold quartz. We learn from Mr. Green that the Bismark Co., who are running a tunnel on Albion hill, struck a fine quartz stringer, and that they intend following it to a large quartz ledge located by the company. The stringer is a good-sized one, and prospects well. The San Francisco copper mine, at Spenceville, is doing well.

A DRIFT CLAIM SPECIMEN.—*Grass Valley Union*: A piece of solid gold was taken out of G. S. Brown's drift gravel claim at You Bet the other day which weighed 1¾ ounces. This is the largest piece ever taken from the ground, although it has been prolific in quarter and half ounce pieces, and, in fact, is one of the richest claims in the county.

PLUMAS.

TAYLOR-PLUMAS MINE.—*Greenville Bulletin*, Apr. 11: The result of the recent run on ore from the dump was not so profitable as had been expected. The previous run on ore taken direct from the mine came fully up to all that Mr. Bransford had looked for. A very marked and most favorable change has occurred in the face of the main tunnel. All the way in the ground had been exceedingly hard and difficult to work, but lately the character suddenly changed; the ground has become soft, and most of it can be worked with the pick; whereas, before this change every pound of the rock had to be torn out with powder. As was to be expected, when softer ground was entered, the ledge matter widened out; in the hardest ground there were places where the ledge was not much over one foot wide; now it is about five feet wide. This is not all solid ore, but consists partly of stringers with soft dirt between.

CRESCENT MINE.—When the Cherokee property was attached and sold, Mr. Davis bought a lot of machinery for which he paid \$300; the lot included a mine pump, gear wheels and shafting. The machinery was taken to the Crescent mine and set up, the pump being worked by steam power. In the mean time preparation was being made to utilize the shafting and gear wheels for doing the work of pumping and hoisting by water power instead of steam; this now is accomplished. Two hurdy wheels are so arranged that one runs the pump and the other the hoisting gear. The power is under as complete control as if supplied by a steam engine. Should the necessity arise to use steam, the engine can be employed by simply joining the connecting rod with the crank pin. In the mill 12 stamps are running. From the dump a few pieces of ore were picked up haphazard, and when these were washed off they were found to be thickly spotted with gold.

GREEN MOUNTAIN MINE.—But little work has been done in the mills during the past week. The ditch sustained damage in several places from the storm, and till these were repaired the water had to be shut off. The same cause kept the air compressor idle, so that not much progress has been made in the tunnel since our last issue. The ditch is now fully repaired, however, the water is turned on again, and work in the mills and tunnel going ahead as usual. About the end of this month the tunnel will reach the ledge.

SHASTA.

SOUTH FORK.—*Cor. Shasta Courier*, April 14: Robinson & Co. have relocated the Big Central and are taking out some excellent ore. A test run, just completed, gave full satisfaction. The indications are favorable for a permanently paying mine. J. B. Strong is mining again, with good prospects. Crum's arastra is running on Wright & Hoskin's ore. E. L. Ballou's arastra is running on Smith & Cooper's ore, but will start on Dunham & Kingsbury's in a few days, as Post has nearly finished packing their ore over. Smith & Cooper's arastra is well under way, and will be completed soon. A tunnel is being run on the Manzanita to tap the shaft; it will take about ten days more to make the connection. Smith & Mosher are sinking on a promising ledge northwest of the Hope, R. A. Brown reports plenty of water in Salt creek. Himself and partner have opened up their ledge in good shape, and have 50 or 100 tons of ore in the slope. Their arastra was running smoothly.

TUOLUMNE.

BONDED.—*Tuolumne Independent*. C. F. Draper, of Oakland, and Oliver Holden, of San Jose, have bonded a one sixth interest of A. Stoddard, and also a one sixth interest of E. C. Herbert, in the Rising Sun copper mine, about four miles southeast of Jacksonville, for \$1,500 for each share, paying down \$500 in cash on each, and the balance of \$1,000 to each party to be paid on or prior to January 31, 1884. The parties agree to work the mine as soon as they can arrange with other owners, and money due may be paid out of the first net proceeds of said interests.

WASHOE DISTRICT.

UNION CON.—*Enterprise*, April 14: At the east end of the joint Sierra Nevada east crosscut, on the 2900 level, a chamber is being cut out for a large winze, which will be sunk to the 3100 level.

MEXICAN.—The east crosscut from the 3100 station, joint with Ophir, has passed through the black porphyry, and is now in vein material of a favorable appearance which contains streaks of quartz that yields low assays.

HALE AND NORCROSS.—A drift has been run south on the 2600 level between the seams of quartz cut some time since near the east wall. From this drift cross-sections have been made east and west. The seams have been found to widen somewhat, and ore is found which assays as high as \$90. A drill hole has been run west, from which material assaying \$30 has been obtained.

POTOM.—Explorations are being made with the diamond drill from the end of the south drift on the 2600 level. Thus far a good deal of water has been found and it has been necessary to plug up some of the holes and start in a new direction.

CON. VIRGINIA.—Work is still in progress in the southeast drift on the 2500 level but it is intensely hot at the face, and it may be necessary to discontinue drifting for a time in order to allow the hot water to drain out.

SIERRA NEVADA.—A chamber is being excavated at the east end of the joint Union Con. east crosscut on the 2900 level, from which a large winze will be sunk to the 3100 level.

ALTA.—Work is now progressing at both ends of the drain drift which is to connect the shaft with the Sintro tunnel.

OPHIR.—The joint Mexican east crosscut from the 3100 station has passed through the belt of black porphyry which forms a kind of horse in the vein, and has now entered the usual channel of vein material.

NORTH GOULD AND CURRY.—The rock at the bottom of the shaft continues to work well. It shows occasional seams of quartz of a good appearance.

GALENA DISTRICT.

STRIKE IN THE McEWEEN TUNNEL.—*Battle Mountain Messenger*, April 14: "A rich strike was made in the McEween mine, at Galena, last Saturday, by the miners working in the main tunnel. The face of the tunnel is nearly all ore, and about three feet of it is very rich. Persons who have seen the bonanza say that it is the richest prospect that they have ever seen. The tunnel is now in nearly 1,000 ft, well timbered, where necessary, with a good track and cars, but little water to retard operations, and the ground is easily prospected. About 135 ft of ledge carrying rich galena ore is exposed in the tunnel, which, at the present face, is about 200 ft in depth from the surface, giving a fine bank for a slope. The full extent of the new find cannot be estimated at present, but it should certainly cause a stir in the camp and be the means of inducing those interested in mines to thoroughly prospect their claims. The McEween mine is owned by Messrs. Blossom & Foster, who have expended considerable capital in opening up their mine, and now will be amply repaid for their expenditure. We are satisfied that there are many more properties in the vicinity just as valuable, if developed."

REESE RIVER DISTRICT.

STRIKE IN THE MANHATTAN.—*Reese River Review*, April 16: A very valuable strike was made this morning, at the bottom of the Paxton incline, at a depth of 1,500 ft. The ledge is large and mostly of a high grade. It shows well in ruby silver and staphanite, and the piece of ore shown us will assay considerably over \$2,000 per ton. This is the most valuable strike made on Lander Hill for some time past, and proves the continued permanency as depth is attained. This development will inspire renewed confidence in the old reliable Lander Hill, and bring good cheer to all in any way interested in Reese River Mining District.

SACRAMENTO DISTRICT.

ORE.—*Silver State*, April 14: Sacramento district, which is situated in the Humboldt range about 10 miles from Rye Patch, is receiving considerable attention from mining men at present. The Boston and Philadelphia mines, recently sold to Oakland men by H. J. Bender, are producing considerable ore which assays from \$50 to \$1,000 per ton. The purchasers intend building a 10-stamp mill on the mines just as soon as the machinery can be brought from San Francisco. R. H. Hope and Jack Bennett, who have been for years prospecting and developing mines in the district, have sold several claims and bonded others. In early days rich ore was found in many places in Sacramento district, and quite a little village, which was first named Williamsburg, and afterwards changed to Lima, sprung up. The latter became known among the miners as Limerick, and that is the name the canyon is now called. The village was abandoned and the buildings, which were principally built of stone and mud, fell into ruins, Hope and Horn being the only persons, who resided in the camp for years.

Arizona.

DOS CABEZAS.—*Cor. Tombstone Republican*, April 14: The future great gold camp of Arizona is not gaining that pre-eminent position as rapidly as we had anticipated. There is but little activity in mining matters to record. The late Indian outbreak has borne its usual fruit, and claim owners have not yet recovered from the feeling of despondency caused by that event. We know the result will be the discouragement of capitalists, who otherwise might take hold of some of the promising prospects in this vicinity, and the consequent postponement of our days of prosperity to an indefinite period. But not-

withstanding this, confident of the superiority of our district, the people are in the main not discouraged.

AN ASTONISHING RUN.—*Silver Belt*, April 14: The Takoma smelter stopped running on Wednesday. It will be idle for a short time. During the last 21 hours they ran 16,000 pounds of copper bullion; and in 45 hours, 20,000 pounds of copper and 17,000 pounds of matte. The matte carries 84% of copper, which would make an actual product of that metal, for the 41 hours, of 43,280 pounds, or a fraction over 1,055 pounds an hour. The largest known product in 24 hours, before this performance, was in the case of the Old Dominion, when they produced about 21,000 pounds. It must be borne in mind that, in the case of the Takoma, as in that of the Old Dominion, only one 30-ton water jacket was used, and the ore was not selected with a view to making a phenomenal record. Globe challenges the world to equal it.

THE TOTAL WRECK MINE.—The mine is located within eight miles of Pantano, on the S. P. railroad, and is only a few hours ride from Tucson. From the depot to the mine there is a good road of easy grade. Quite a town has grown up, and a large number of people are employed. The greatest depth reached is 340 ft. Between that and the surface are four levels, all of which have developments which prove the continuity of the ore body. On one of the levels the ore breast showed 27 ft, and on of the walls only—the footwalls—had been reached.

DOS CABEZAS.—*Cor. Tombstone Epitaph*, April 14: The copper mines of this district are exciting capitalists by their wonderful developments of the past month. Scarcely a day passes but some new find is reported, and so the interest increases day by day. Many of the mines can show ore that will run 40% copper and \$200 silver. Some ore was on exhibition in town to-day from the Copper Whale, owned by Charles Williamson, Corey and Porter, that will run almost 60% copper and over \$100 silver, and beside this high grade ore there is in this mine an immense amount of ore that will run 15% to 20% copper. The intrinsic worth of this and other mines of the district in gold, silver and copper is fully one half greater than many mines in more inaccessible places that have created such excitements. The Dos Cabezas mines are all comparatively easy of access, only 14 miles from the railroad, plenty of water near the mines for smelters or mills, and the actual value of the mines must call at no distant day the attention of capitalists and mining men, then many will wonder why such valuable properties were allowed to lay idle so long. Among the other promising copper prospects is the extension of the Copper Whale, owned by P. A. Boyer; also a copper mine owned by John Burt, on the north side of the mountain. John Casey is getting ready to start his arastras on ore from the Juniper mine. Johnson has done a great amount of work on the Silver Cave mine this spring. He has taken out several tons of rock for his arastra mill. Some of the ore goes as high as \$80 gold, and some as low as \$14 gold. The \$14 ore is quarried down from a ledge forty ft wide that stands out of the ground nearly one hundred ft. The \$80 ore is taken from a ledge in the back end of crosscut tunnel.

Colorado.

THE GRANT SMELTER.—*Denver Journal of Commerce*: The Grant Smelter shipped upwards of half a million in bullion in the month of March, and will increase the output the present month. The books of the concern show that \$545,050 was the March product, and is the largest shipment ever made in one month by any smelter, mill or other reduction works in Colorado. The amount of ore treated was 8,350 tons. The amount of bullion shipped during the month represents very closely the month's product, as the bullion is shipped with little or no delay, and does not accumulate from one month to another. It was produced in eight stacks. The new ninth stack has been running for about a week but did not effect last month's product. The average daily work of a stack is therefore the reduction of 33½ tons of ore. It is not likely that a much higher average than this could be reached. The average amount treated daily is 270 tons. The highest amount treated in one day during the month was 307 tons, or 38½ tons to the stack. This is a fair test of the actual capacity of the stacks with the charges then used, as they were running under a blast pressure which caused the slag to spout from the tap-hole in a stream that fell clear off the gutter which usually conducts it to the slag-pots. The new stack is similar to the others and consequently with similar ore and a smooth run there will probably be over 9,000 tons treated during the present month and over \$600,000 of bullion produced.

Idaho.

WOOD RIVER REGION.—*Ketchum Keystone*, April 6: The ore in this region is generally galena and gray or sand carbonates, with an average assay of 100 ounces per ton. The general direction of ledges in the northwest and southeast, pitching, if at all, westward. The general formation is porphyry and lime. All are well located for natural advantages.

WARM SPRING CREEK DISTRICT.—The Irwin situated on Warm Spring creek, 15 miles distant from Ketchum, is developed by means of 500 ft of tunneling, and presents an average ore body of 2 ft. Upwards of 1000 tons lie dumped ready for shipment, 8 men have been employed to date, and the prospects are favorable for an increased force immediately.

POOR MAN, one and one half miles southeast of the Irwin, and owned by independent parties, is located in Poor Man's gulch. At present being lightly prospected, it is developed by a 150 ft tunnel which shows in its breast a fine ore body.

WEST FORK, owned and operated by the same company (Philadelphia) is 7 miles distant and is developed by means of several surface cuts, and at the present time is being tapped by a 500 ft tunnel at a depth of 1000 ft. Two hundred and twenty-five tons of good ore lie on the dumps of the Black Hawk, an adjoining claim which runs parallel to the former and consists of a very similar vein. Average width 8 ft; grade, 90 ounces. Amount of work done, 252 ft shaft. Force employed to date, 10 men. Probable force for the season much larger. The Penbrooke is another very promising prospect of the same company situated near the Irwin, which will be worked by a moderate crew during the summer. The Night Hawk joining the Black Hawk on the northwest, and owned by Messrs. Connor McLeod and McGregor, is developed by a 70 ft shaft and 2 tunnels respectively 30 and 40 ft, disclosing a vein very similar to that of the latter being a continuation.

THE ONTARIO.—This mine is owned by the W. S. C. M. Co., is situated in the Boyle Mountain vicinity about 15 miles distant. The mine has undergone considerable development, having been worked all last summer by 10 men and a small force during the winter. There is about 650 ft tunnelings. The breast of the main tunnel exhibits a fine ore body with an average width of 30 inches. Several hundred tons of good smelting ore lies on the dump ready for shipment. The grade is higher than is usual in that region, often going over 200 ounces per ton.

Montana.

MADISON CO. MINES.—*Madisonian*, April 10: Mr. Henry Miller, who has been engaged during the last winter in developing the quartz mines in Barton's gulch, furnishes us with the following items from that promising district, which is situated a short distance from Virginia City. The most extensively developed mines in the district are the Black Eagle, owned by J. W. Morris, Kyle Bros. and C. Gibbons; the Gray Eagle, Capt. W. L. Southmayd; the True Fissure, Gibson & McCullough; the Zelra, Hyndman & Jobb; the Palmyra, A. Garrett; the Old Union, K. T. Cook, and the Little Annie, Henry Miller. The Black Eagle is situated up the gulch, about four miles from the Ruby valley road. It is opened by three shafts, one of which is 170 ft deep, showing ore which assays \$230 per ton; the second, 250 feet eastward of No. 1, is about 40 ft deep, in a three-foot vein of similar rock, and the third has been started 150 ft further east, and shows a two and a half-foot crevice. The ore is easily worked, and a shipment to Salt Lake netted \$122 per ton to the shippers. About 300 ft above this mine is the Gray Eagle, which has been bonded to an Eastern company, which has a representative now on the way here, with instructions to thoroughly develop the mine this season. From the showing already made, there is a strong indication that it is a first-class mine. Half a mile east of the Gray Eagle is the True Fissure, opened by a shaft and tunnel, and showing a good quality of ore. It has a six-foot crevice. The Zelra is 400 yards east of the True Fissure, and Messrs. Hyndman & Jobb have sunk a 100-foot shaft on the mine, and have run a tunnel 150 ft. The latter will tap the lode this spring. Half a mile southeast of this is the Old Union, a very extensive mine, being over 40 ft between the walls, with good ore in sight, and plenty of it. The Palmyra, 200 yards above, also shows a good body of rich ore. The Little Annie has been opened by two shafts, and has a wide vein. The ore body is large, two and one-half ft on the hanging wall, and one foot on the footwall, being very rich. Messrs. Emery & Garrett are working on the Agriola, with very good prospects. Several other lodes have been discovered in the district, and are quite promising in appearance, though not yet developed to any great extent. The lodes are gold and silver bearing, with some galena and copper, and are unmistakably permanent and true fissure veins. The work already done shows that the district presents an inviting field for the investment of capital in the erection of reduction works, and, when this is done, we may look for a lively mining camp in that neighborhood.

THE DRUM LUMMON.—*Inter-Mountain*, April 12: In the magnitude and uniform richness of its ore body, the Drum Lummion mine, in Marysville district, in Lewis and Clarke county, is, perhaps, without a peer in Montana among the gold and silver mines, and it is most gratifying to know that it is to be worked on a scale commensurate with its known value. While the Drum Lummion is not a developed mine of ascertained permanence and strength of ledge like the Lexington and other prominent silver mines of Butte, the surface workings have shown up such immense deposits of ore, which is in some places 10 ft wide, that its right to be called a great property cannot be reasonably disputed. Even, with the present limited openings in the mine, the extraction of 100 tons of ore per day for several years would in no sense tax its productive capacity, from which statement of fact it readily appears that the company is taking no chances in making the expenditures necessary for the erection of a 60-stamp mill, which we learn on good authority has been fully determined upon. The old mill, with which Uncle Tommy Cruse has been pounding away on Drum Lummion ore for several years past and getting out about 40% of its value, will also be refitted, and will be used to make test runs on the several qualities of ore which may be discovered in the mine, in order to demonstrate the grade of its milling character. The Drum Lummion is an immense property, and, with good management, its development will result in immense profits to the stockholders.

New Mexico.

COPPER MINE SALE.—*Southwest Sentinel*, April 14: We are reliably informed that the sale of the Burro Mountain district copper mines and the extensive works of the Valverde and Queen City Cos., that has been pending for some time past, has just been consummated and that the money has all been paid into the hands of the trustees, to be turned over as soon as the necessary title papers can be made out, and the usual preliminary arrangements gone through. The claims sold, include the entire property of the Queen City Co. and of the Valverde M. & S. Co. and 60 other mines, covering in all 9 square miles of mineral land. This sale is one of the most important that has occurred in New Mexico for many months, the actual price paid being \$1,500,000 in cash. The English Co. has reserved \$1,000,000 for a working capital to open and develop the mines and to extend and enlarge the reduction works already erected.

Utah.

THE MINING OUTLOOK AT PARK CITY.—*Salt Lake Tribune*, April 14: The Apex M. Co., is a corporation formed under the laws of Utah Territory, and comprises eight patented claims, viz. Brave Columbia, Constitution, Cumberland, Monroe Doctrine, Hannah, Antelope, Gazelle and Daylight, and portions of other claims which have been patented. This group of claims contain an area of over fifty acres, and adjoin the Crescent and Walker and Webster properties. In fact, the three properties lie together. Since the formation of the Co., work has been pushed forward on the property with gratifying results. The mining outlook at the Park is promising at this time, and with the shipment of ore from the Crescent, and the output from the Ontario, the present year will add considerable to the bullion product of the Territory.

The Prospects of the Comstock Lode.

To the San Francisco Stock and Exchange Board—Gentlemen: Your investigating Committee beg leave to submit the following report as to the condition of the Comstock mines:

We have found it impossible to obtain any reliable official information with reference to the condition of the mines, and the little we have been able to glean from that source is anything but satisfactory. This is owing to the secrecy with which all explanatory work is carried on, through the medium of the diamond drill, which has been extensively used in almost every mine on the lode, while the result of such explorations is kept a profound secret by the operators, who have obtained control of the different companies, chiefly by means of proxies, which have been voted at the annual elections. While the State laws have made it imperative, on the part of the superintendents, to report to the companies' officers all discoveries made with the diamond drill, we find that they have, in almost every instance, disregarded the law, contenting themselves with privately reporting such discoveries to operators who have obtained such control, while having little, if any, moneyed interest in the companies. This is a matter of grave import to the stockholders of the companies, who, while paying enormous sums for the purposes of exploration, are debarred all knowledge of, or benefit from any discoveries which may be the result of such expenditures. It is true, that reports are made to the secretaries of

drained. Nothing but the grossest carelessness could cause any damage from water. So far as we are able to judge from the vague reports in the different offices, and what reliable information we have been able to obtain from other sources, there is every probability that some of these mines will be on a dividend-paying basis ere long, and the long suffering stockholders be relieved from the terrible exactions in the shape of assessments under which they have groaned for such a length of time.

These mines are splendidly equipped with machinery of the finest and most substantial character, their pumping machinery being unequaled in the world. The mines are opened to great depth, the deepest workings being in the Mexican and Ophir, on the 3100-foot level. They have large and substantial shafts and winzes, and are opened laterally with large drifts for about two miles, and so well arranged and connected as to make danger from fire a very remote contingency.

For about a mile north of Savage, no explorations of any importance that we are aware of have been made on the lower levels until very recently, when several crosscuts were started, one of which encountered ore on the line of the Union Con. and Sierra Nevada of great promise, and we have good reason to hope that when further explored it will prove a real bonanza. The other crosscuts so far give good indications, and we expect to see paying ore developed by them.

The Savage, Hale & Norcross, Chollar, and

will say that in our next report we will deal more fully with the subject of mine management. In conclusion we would say that the prospects and conditions of the mines on the Comstock lode have not been so good for years, and that we believe that in the near future the Comstock lode will be restored to the proud position it once held as the greatest bullion producer on the globe.—M. J. McDonald, Marcus P. Hall, Sam'l Dixon, J. McKenzie, J. M. Shotwell, R. F. Rogers, Coll Deane.

The report was placed on file. A discussion was held regarding the advisability of publishing the committee's report and it was decided that it was inexpedient for the Board, as a Board, to officially authorize the publication of a report submitted at a private session.

Reduction Works for Arizona.

It has been stated, evidently by persons who had not given the subject proper thought, that in the erection of reduction works in Tucson, a capital ranging from \$15,000 to \$20,000 would be sufficient to cover all possible contingencies. This is a grave mistake, and were it made, it would result disastrously to the enterprise and to the prospects of this city as a mining center. To erect proper works capable of treating all classes of ore in an economic manner, would require the expenditure of no less than \$100,000, and from that sum up to \$250,000, according to the magnitude of the proposed undertaking.

subject and a proper presentation of the matter would probably meet with favorable consideration.—*Arizona Citizen*.

The City of San Diego.

The city of San Diego is beautifully situated upon ground rising gradually from the shore, with just sufficient elevation to furnish good natural drainage, and give the place quite an imposing appearance as it is approached from the sea. The natural advantages of the town for a great commercial emporium could hardly be excelled. The harbor itself is, next to San Francisco, the finest on the coast, while the equable temperature of the climate is superior even to that of the famous bay and harbor of Naples. As the steamer from the north rounds Point Loma, the traveler by sea gets his first view of the city of San Diego, by looking directly across the harbor and over the low intervening peninsula, which separates the harbor from the ocean, and with which it is connected by a very narrow entrance, itself also protected by the high promontory on the left, and the low, receding coast line on the right. The harbor is perfectly land-locked, readily distinguished and easily approached. The view of San Diego, which we present, has just been drawn and engraved by W. W. El-

BIRDSEYE VIEW OF SAN DIEGO, SAN DIEGO HARBOR AND THE OUTLYING COUNTRY.

the different companies, but they are very meager and treat only of the most unimportant work going on in the mines, and where reference is made to interesting points on the lode the information given is so vague as to be rather calculated to deceive than to give any proper understanding of the situation. From information, however, obtained outside of official sources regarding the existence of "concealed bonanzas" we are inclined to the belief that valuable ore bodies have been discovered, which so far have not been officially announced. But as we are restricted by our informants in the use of this information we abstain, for the present at the least, from making any more positive statements than the foregoing.

With reference to the middle and northern mines, viz: all those mines situated between Potosi and Utah inclusive, we have to say that they appear to be in a splendid condition for rapid exploration. There has been an enormous amount of money expended upon these mines in preparatory work, such as sinking shafts and winzes, and making air connections, running lateral drifts, etc., and we have every reason to suppose that the cost of future explorations in these properties will be much less than at any time in the past. In fact, it should be possible to run these mines for the next two years for one third of the expense which the work for the past two years has entailed upon the stockholders. These mines are thoroughly ventilated, and, as a rule, much cooler than they have been for some time past. The danger from water is past, the water problem having been solved, and the work now going on is below the water belt, and the mines are well

Potosi, are all ready for crosscutting on the lower levels, and the fact that in Hale & Norcross there has already been some good ore discovered on the 2600-foot level, gives us reason to expect the uncovering of a body of good ore in this section of the lode.

In the Mexican, Ophir, California, Con. Virginia, Best & Belcher, and Gould & Curry mines there is a block of ground about 1,000 feet in height, by over 1,000 feet in width, and over 3,500 feet in length, which has not, so far as your committee is able to learn, been crosscut or explored in any way to any great extent. What may have been done with the diamond drill and secret drifts in this block of ground, of course, is a sealed book so far as your committee and the general public are concerned.

All the lower levels of the Comstock mines are in an ore zone, as shown by the continual cutting of stringers, seams, and small bodies of rich ore, and there is no reason why there should not be large and rich bodies of ore discovered. In fact, the prospects for the lode were never brighter. So far as the southern group of mines is concerned nothing can be seen below the 1900 level, as the mines have been flooded up to that point for more than a year. Above this level there has been a large amount of ore extracted. Within the past two years over 120,000 tons of ore have been extracted and worked—principally from the Crown Point and Belcher. What this ore paid we have been unable to find out, and we can only say that there is an abundance of ore in these mines, and that it is not the fault of the mines that they have not been placed on a paying basis long ago. In this connection we

The company erecting the works, to insure a full supply of ores, must begin to purchase by sample from the start, and the miners and prospectors on every hand stimulated by the certainty of obtaining ready cash for the product of their mines, will bring in ore in quantities from a hundred pounds to that number of tons, and the money derived from its sale will give them means to further develop, and from that time on renewed activity in mining will be the rule, and, as a sequence, the prosperity of the city.

The company must have funds to purchase all the ore offered for sale, and be in condition, if the supply exceeds the capacity of the works, to store it for future manipulation. A company with small capital cannot do this without crippling itself and meeting many financial embarrassments. For lack of proper appliances the small company could not reduce the ores at the small cost the larger works could. The Grant smelter in Denver works ore at an expense of less than five dollars a ton, and ten dollars pays a big profit. Less complete works could hardly work ten dollar ore at all, and as much of the difference in the cost of reduction is the profit of the miner, it is reasonable to suppose that the cheapest cost of reduction will command a greater quantity of comparatively low grade ores, and the venture would be less experimental as an enterprise.

As Tucson must have reduction works its enterprising people should endeavor to induce such men of wealth as the proprietors of the Argo works at Denver, who can afford to spare millions without any embarrassment whatever. Their attention has already been called to this

liott & Co., lithographers and publishers, 421 Montgomery street, S. F.

COPPER IN MOHAVE COUNTY.—The copper mining interests in Mohave county, says the *Alta Arizona*, are destined, in the near future, to take prominent place. There is probably not a mining district in the county that has not met many ledges bearing copper. A great many of the so-called silver mines in the county are rich in copper, while some of the mines are so rich in this useful mineral that but little attention is paid to the other minerals they carry. The copper interest in this Territory is yet in its infancy, giving an output last year of but 15,500,000 pounds, but the day is not far distant when this yield may be exceeded in Mohave county alone, if one half the ledges that now "show up" well shall prove to be good mines. Some mining men have expressed doubts as to the reward that awaits those who engage in the development of the vast deposits of this mineral in our county. Owners of copper mines need have no fears on this score. Late statistics show that the home consumption alone last year was 40,000 tons—but 140,000 pounds less than the entire product of the country.

THE *Industrial Progress* is a neatly printed monthly published by the Inventors' Institute of this city, which we noticed in the *PRESS* some time since, and is devoted to the sale of inventions on commission. A. Budd Smith, manager.

THE ENGINEER.

De Lesseps and his African Sea.

The African inland sea is still a matter of much thought with M. De Lesseps and his friends. That engineer has lately visited the locality of the proposed connecting canal, and, with a party of engineers, taken a horseback ride over the proposed route, and examined that portion of the country which it is proposed to cover with water. The locality of the proposed "inland sea" is not, as generally supposed, upon the desert of Sahara at all, but quite to the north of it, and separated therefrom by a range of mountains, which form the southern boundary of the Regency of Tunis. The "sea" will occupy the site of several marshy lakes in Southern Tunis, and will cover an area only a trifle larger than the little State of Rhode Island, and not quite so large as the valley near the Gulf of California, which an American Engineer has proposed to convert into a lake for a similar purpose.

One of the principal objects of the enterprise is to give water transportation to the seaboard for the timber from the mountains upon its southern and western border. It is thought, moreover, that the moisture which will be engendered by the presence of this body of water will bring into cultivation a vast tract of land, which, although now a desert, was quite celebrated for its fertility during the Carthaginian rule in Africa. The canal will start from a point near the port of Gabes. Exclusive rights over the land and the forests surrounding the "sea" will compensate the company which undertakes to excavate the connecting channel. A preliminary survey has been completed by Commandant Roudaire, and there is no doubt that the level of the lakes is fourteen meters lower than that of the Mediterranean. The chief question now requiring elucidation is the nature of the soil between Gabes and the lakes. If it turns out to be anything but rock, M. de Lesseps thinks there will be no difficulty in speedily carrying out the project, which has occupied his attention ever since it was suggested to him by the Empress of the French at the opening of the Suez canal. Sahara, however, will still remain as much a desert as it ever has been since the commencement of the historic period of time.

THE GREAT STATUE OF LIBERTY.—A singular problem in engineering is presented to the committee which has in charge the construction of the pedestal for the great statue of Liberty in New York harbor. The statue weighs, complete, only about eighty tons, but presents an immense surface to the wind, and stands, moreover, on a comparatively small base. Considering that it is not extremely easy to construct a brick chimney of the same height—one hundred and forty-eight feet—weighing ten times as much, of pyramidal form, and standing on the ground, so as to resist the force of a storm, the difficulty of raising and securing the statue, not on the ground, but on the top of a pedestal nearly one hundred and fifty feet high, is apparent. There are no precedents for anything of the kind, and it will hardly do to secure the figure by the rope stays, like those of a derick, which the incapable engineer would naturally resort to. The members of the committee seem to have perceived something of the difficulty of the undertaking, and have telegraphed to France for instructions as to the mode of doing the work. The *American Architect* suggests, that the plan said to be employed by the Japanese for securing their light pagoda towers against the effects of wind, by means of a long weight or pendulum, hung from the top of the tower, and reaching nearly to the floor, might perhaps be employed with very good effect for the New York statue. A very similar device, applied by Sir Christopher Wren, has for two hundred years held up the spire of Salisbury Cathedral, as well as those of one or two other English churches, in which a heavy wooden framework, extending as far downward as the construction of the tower permits, is suspended by strong iron bars from the capstone, free to swing in any direction. The effort of the wind on one side of the spire inclines it until the hanging framework rests against the opposite side, but when the pressure is relieved, the pendulum swings back, bringing the stonework with it into its original place.

THE BROADWAY, N. Y., TUNNEL IMPRACTICABLE.—There is no use in sighing for the unattainable; and if it is a fact that the obstacles to the construction of a tunnel under Broadway are too great to be surmounted, the public must reconcile itself to disappointment on that score. That the project is impracticable, at least upon any plan thus far proposed, is the conclusion at which the commissioners appointed by the Supreme Court to investigate the subject have arrived. The chief difficulties named by them are the interruption of traffic during the two or three years which it is estimated the work would occupy, and the damage to which the foundations of buildings would be liable from the necessary excavation of the street. It is not held that the accomplishment of the work is absolutely beyond the reach of engineering science in its present state, provided sufficient time and money are at command; but the commissioners are not of the opinion that the scheme in its present shape is feasible, and they also doubt whether the tunnel road, even if completed, would supply the needs which it is intended to meet.

USEFUL INFORMATION.

IMPROVED FOOT WARMERS.—M. Anceelin, a French experimentalist and the discoverer of heating with crystalline acetate of soda, has demonstrated the much slower cooling of foot warmers containing that substance than that of the ordinary ones with water. Two leading French lines of railway have this system in general use, and in England the London and North-western railway, which had last year 3000 of such warmers in service, has this year 6000. Applications of the system have also been made in Italy, Spain and Portugal; and it is pointed out that among other applications of the same principle are the heaters for beds, dishes, pontics, muffs and feeding bottles. But Mr. Anceelin, in an article contributed to *La Nature*, remarks that the operation of filling the warmers requires certain precautions to avoid suffusion or supersaturation, which the acetate is liable to in a closed vessel. This phenomenon is apt to occur, especially if there is an excess of water in the acetate—a fact due often to the moisture in the air, which the substance readily absorbs. The precautions consist mainly in elimination or saturation of this excess of water, and also in the employment in the warmer of a spherical reservoir of crystals, with thick walls of a material which conducts heat badly. This reservoir also acts in destroying supersaturation by the vibration it imparts to the liquid salt during the train's motion.

IMPROVEMENTS IN MAKING GLASS.—The high expectations in regard to toughened glass can scarcely be said to have been realized as yet, and several improvements must yet be made before the process can be considered as perfect. The original method consisted in immersing the article while still red hot in a bath of oil heated to 200 degrees C. (392 degrees Fahr.), and letting it remain there until it had cooled down to that temperature.

T. Lubisch claims to have discovered a better method of hardening glass, or, rather, an improvement on the same process. He also immerses the article while red hot into a hot bath, but he takes it out again when it has nearly lost its redness, and lets it cool very slowly in an oven that is heated nearly to the temperature of the glass. As the bath does not need to be much above 212 degrees Fahr., he prefers to use solutions of the carbohydrates in water (starch, gum, or the like.) Such a bath does not soil the surface of the glass, as is the case with fats, oil, and bituminous substances.

Glasses subjected to this operation resist pressure and shock just as well as those hardened in oil, but possess this advantage, that they can be cut with a diamond, or polished and cut with sandstones. While the oil method only permits of the hardening of articles of simple shape, by Lubisch's process all glass things can be hardened—as, for example, all bottles, mugs with handles, pitchers and other vessels.

NEW TEST FOR WASTE PIPES.—A Boston paper relates a discovery which may prove to be a better test for leaky waste pipes than heretofore used. The invention is accorded to a woman. Noticing an offensive odor in the parlor, she suspected a defect in the waste pipes, and sent to the agent to request that a plumber might be sent to examine them. The agent was incredulous, and refused. She tried the peppermint test. To make her proofs more convincing, the woman, after borrowing two cats from her friends, purchased some oil of valerian, and stationing the animals in the parlor, went up stairs and poured the valerian into the basin in the same way that the peppermint had been applied, and then descended to watch the result. Cats are extremely fond of the odor of valerian, and it was not long before both of them began to sniff the air, and move toward the door of a closet through which the waste pipe ran. The door was opened for them, and they immediately sprang upon a certain shelf, where they remained purring with satisfaction. A third time the woman went to the agent, who, though still unbelieving, consented to send a plumber to make further investigations, and, on cutting away the plastering so as to expose the pipe, a joint was found completely separated at the place where the cats had indicated.

MORE NEW USES FOR COTTON.—It is said it has been demonstrated that fire and water-proof houses can be built out of cotton and straw. The cotton used is the refuse of the plantations and factories, and when ground up with about an equal amount of straw and asbestos, is converted into a paste, and subsequently into large slabs or bricks, which becomes as hard as stone. The article thus made is pronounced the best of architectural material, and will be much used. A Boston rope maker of long experience, like the father before him, says that cotton rope can be made for fifty per cent. less than hemp, and is preferable for all shipping uses, cables, bolt, rope halyards, tow ropes, hawser, tackle and falls, hoisting, etc. He also says that cotton is superior to hemp for caulking, and believes that it can be used for roofing and as a substitute for leather and rubber in hose and belting, and for tubing to inclose telegraph and telephone wires, both over head and under ground. He states that 150 tons of hemp rope is made in the United States daily, the material for which is mostly imported. Congress has authorized the Secretary of the Navy to intro-

duce cotton cordage into the naval service of the United States, to such an extent as will fully test its value and efficiency, as compared with the kinds now in use.—*Industrial South.*

ASBESTOS ROPE.—Asbestos rope is described among other articles now being turned out by the United Asbestos Co. of Great Britain. The strength seemed to be about one fourth that of ordinary hemp rope of the same diameter. Rope one and one half inches in diameter is stated to have a breaking strength of one ton, and twenty feet of it weighs thirteen and one fourth pounds. It is made especially for fire-escape purposes, for theatres, fire-brigades, and for ready means of escape from houses and public buildings; its advantage being that it will not break and drop its burden if a flame bears upon it. It is made like ordinary rope, but spun from Italian asbestos thread, and there seems to be every probability of its favorable reception by the public.

TO DEODORIZE KITCHEN ARTICLES, cover them with charcoal dust, place them in an enclosed vessel, and raise the temperature to 94 F.; let it remain thus for several hours; remove and clean the articles from the dust, and they will be found, says a contemporary, free from all odor.

LUMINOUS PAINT is now used to illuminate the faces of clocks, watches and door plates. It may easily be made as it consists merely of a compound of lime, sulphur and varnish.

GOOD HEALTH.

Arsenic for the Complexion.

Speaking of the weakness of the gentler sex, says a Cleveland correspondent, I met my friend, the doctor, yesterday, and as he and I stood and surveyed the passing show, a plump, fair woman passed by, and I said to him, "What a charming complexion!" "Short lived, though, my dear boy," quoth he. I expressed surprise, for my charmer was young. "Arsenic, Talbot, arsenic!" said he calmly. Then it dawned upon me what he meant. Resuming, he said: "Its use is increasing. Women eat it in two forms: the white powder, that caused poor Jennie Cramer's death, or arsenious acid, as the drug dealers have it, and Fowler's solution, which the pharmacopoeia says is a mixture of arsenic with potash in the fluid form. Either way of taking arsenic produces the plumpness of face and beauty of complexion that you noticed in your fair lady. Its influence is principally on the capillary system of the skin, which produces the plumpness. In plain English, water is the influence at work, and in the end it shows itself. The skin assumes a watery transparency, which in its turn gives way to ghostliness and whitening of the lips. This is the awakening from a blissful dream. Beauty vanishes and the end comes. Horrible? Oh, no! I call it retribution. Cynical? Perhaps! but plain truth generally is, my dear boy, in these days of ours. Arsenic eating can be stopped at any time without an effort, except that which vanity dreads. It has none of the soporific effect of opium or morphine. Used as a medicine, it is an excellent tonic, one of the best known."

"How long can arsenic be used before it produces the ghostliness you speak of?" I asked my mentor.

"Six weeks' unbroken dosing will do the work well and effectually," answered he; "but woman is skillful, and using it a week she pauses, and before the effect of the cessation comes she takes another interval of arsenic dosing. This fate is held off. The end must come, however, and it comes all too soon for the arsenic eaters. Some systems agree with the drug longer than others, but a few years of the periodical eating settles it."

You Cannot Kill a Pig with Arsenic.

"It is an astonishing thing," went on the cynic, "that you cannot kill a pig with arsenic. I had a friend who was an enthusiastic chemist. He had preserved a lot of cherries in an arsenical solution, and having no further use for them threw them one morning from his laboratory window. A rambling porker, on the lookout for edible trifles, saw them drop, and looking them over and contrasting them with the usual expanse of tile, brickbat and old tin cans on which it had been his daily wont to browse, eagerly swallowed them. My friend was alarmed, and visions of a bill for the value of a dead and uncatchable pig rose like a spectre before his eyes. He chased the pig away, and thought perhaps its death might not be laid at his door if the pig was not there when it expired. The incident warned him; but on the following morning he was dumfounded to see the pig waiting for more of the deadly fruit. Some were prepared, for my friend was an investigator, and doled out to his hogship. He devoured them, and grunted a muffled paean in their praise. Each morning that pig returned, and each morning the dose was increased until my friend was ruined and the pig's confidence in arsenical cherries stronger than ever."

SLATES BAD FOR THE EYES.—Professor H. Cohn, of Breslau, believes that the use of slates by school children tends to produce short sightedness; and would substitute either pen and ink or an artificial white slate with black pencil, manufactured in Pilsen, and al-

ready introduced into a few German schools. In 1878 Horner found that B and E could be read, if black on white ground, 496 cm.; if white on black, 421 cm.; and if gray on black, 330 cm.; and ascribed the greater difficulty with white letters to irradiation. The reflection of light from the surface of slates is, it is said, enough alone to cause their disuse. The school board of Zurich has forbidden the use of the slate after the first term (primary year), and many teachers and oculists advocate the substitution of white-boards for blackboards. The noise of slates: dirty habits formed by erasures; bad positions favored by reading the less legible script; a heavy hand; and the habit of twisting, learned with a pencil, and to be unlearned with a pen—these, it is said, are obviated by the use of pen and ink at the outset. The obvious objections are, that children can occupy themselves better with slates, and from pencil to pen is from the easier to the harder.

Scientific Nursing.

There is no subject of so much general interest as this, concerning which there is, at the same time, such a widely prevalent ignorance. There are few, especially among women, upon whom will not devolve, at some time in their lives, the care of the sick; fewer still, who will not at some time become dependent upon such care; and it might naturally be supposed that matters of such primary and universal importance as sanitary conditions and the practical application in the sick room of scientific principles would be too familiar to every one to need to be further enlarged upon. But the fact is, it too frequently happens that all the scientific knowledge which ever enters the sick room comes in with the doctor and goes out again with him. This state of things requires to be improved. Knowledge, and that correct knowledge we call science, is just as indispensable to the nurse as to anybody else.

It is a great mistake to suppose that all women—even good women—make good nurses. The best intuition and the tenderest heart may co-exist with an utter lack of executive ability, and be more than counterbalanced by ignorance and prejudice. Native aptitude gives advantage, but it cannot be relied upon alone. Even those who possess in the highest degree the natural gift of ministrations which renders them so acceptable to the invalid, would find their power of usefulness very largely increased by a familiarity with what may be properly called the science of the sick room. Physicians are recognizing more and more the importance of hygienic agencies in the treatment of disease, and with this there has come an increasingly urgent call for the scientific instruction and practical training of those who are to take charge of invalids. Science explains the conditions upon which the art of the nurse depends, and lays down principles which can not be violated without injury; but it is not at all necessary to make a parade of technical language in stating its requirements. *Popular Science Monthly.*

How to Feed Babies.

Dr. H. Gibbons, Jr., gave an interesting lecture at Cooper College last week on baby food, taking the ground that the system of nursing by artificial food was very destructive to children's health. He claimed that in San Francisco one death in every 300 was attributable to improper diet, and one in every 200 in New York. Taking the average, 250, for the United States, he said we have 200,000 infants whose deaths are the result of improper food. For natural food no substitute has yet been found, unless it be cow's milk, which, though not of course as good, answers the purpose. Wet nurses, he thought, were better than cow's milk. The statistics showed that of 100 children nursed by their mothers eighteen per cent. had died, while of 100 nursed by wet nurses twenty-nine per cent. had died in the first year.

A striking example of the fallacy of the artificial food theory, he said, was furnished by a London hospital. Nineteen per cent. of those cared for by wet nurses had died, while of those nursed by artificial food fifty-four per cent. had died. Of one hundred children nursed by their mothers sixty-three were healthy, twenty-three tolerably so, and fourteen sickly. Of those half nursed fifty-two were healthy, sixteen tolerably so and thirty-two sickly, while of one hundred children fed on artificial food, ten were healthy, twenty-six tolerably so and sixty-four sickly. A practice injurious to a child's health is, he said, that of nursing immediately after birth; another, that of nursing at night, as a child's stomach, as well as an adult's, needed rest. If the milk was insufficient, he said, other food might be added, as this was better than frequent nursing and overloading the stomach. He recommended fasting during illness, instead of constant feeding, and advised the giving of a drink of barley water before nursing, especially in hot weather.

BLOOD INJECTION IN SURGERY. Dr. Labbe recently removed a wen weighing eight pounds from the neck of a young woman. He then injected one pound of blood, taken from the arm of a medical student into her veins, and so saved her life. The student is to be fed on the best of the food till he makes up for his loss—a matter of a few days.

Passing Events.

The rains have come again this week and are welcome to the country. The water season this year will be comparatively short no doubt, and all the rain that falls is so much gained.

Spring has fairly opened, and the prospectors are now all over the hills. In the southern counties particularly is this the case. Still, further north prospecting has begun. Up at Wood river the spring is six weeks in advance of the season. Relocating has placed many good prospects in industrious hands.

The only strike of consequence of late has been at Tuscarora, Nev. In the mine where the strike was made a short time ago an ore seam was discovered on the surface that led to the conclusion that an extensive ore body existed deeper down. In order to determine this fact a drift was projected in the direction of the surface indications. This level had reached a distance of forty or forty-five feet when the ore body was encountered, following a hanging wall. A crosscut was immediately started to determine the width of the ore body. The crosscut is in six feet, and no wall is reached yet. The ledge is widening rapidly, and gives promise of being the heaviest ore body ever discovered in this district. The entire gangue, as far as opened, gives an average assay of \$300 per ton. A chloride seam of twelve inches, following the footwall, gives a return of \$853.50 per ton.

The Center Core System of Tunneling.

The early tunnels of modern times were all built for canals, and railroad construction did not commence until between 1825 and 1830. The canal tunnels of the last century were, with few exceptions, narrow ones; but about the beginning of this century tunnels of a wider cross section began to be driven. Moreover, the earlier English canals were through rock. The Tronquoy tunnel in France, on the St. Quentin canal, built in 1803, seems to be the first in which a system of timbering and arching for supporting soft and loose ground had to be devised for a wide tunnel—twenty-six feet. On starting this tunnel, we are told by Mr. Drinker, in his work on "tunneling," that the engineers adopted a system of construction which was, in fact, simply an extension of the old small heading timbering in loose ground, with caps and legs. In the plan adopted a heading was driven, and the foundations for the abutments laid in it; then a second heading, and above it another, the masonry being successively carried up in each.

After these three sections as they may be called, had been successively erected, the top was excavated across and connection effected between the two sides. In the top the arch was complete. No centers were used, the arch being built on a mound of well rammed earth. Finally, after the completion of the arch, the center core was removed.

This was the origin of the center core system, and so far as the center core alone is concerned the system should be called French, as it originated in a French tunnel. It is called, however, the German or center core system. The Germans adopted and used in their early tunnels the center core system in full, building their abutments first (as was done at Tronquoy) and arch afterwards, hence the distinctive term "German" is applied to this plan of work.

The French engineers, however, have later inclined to a system what is a sort of middle course between the Belgian and center core system, and which, no less an authority than Mr. Henry S. Drinker says, embodies the worst features of both.

This primitive system of construction was improved on at the St. Aignan tunnel in 1822. A heading nine feet high was driven at the top of tunnel; then steps were dug down on either side, a core being left in the middle. The abutments were put in, the arch turned, and the center core taken out. In 1824, a further improvement was made in the Pouilly tunnel. Two adits were driven on either side of the tunnel, and on these the foundations and abutments were made. Then a top-heading was driven and enlarged. In this space the arch is turned, and finally the core taken out. The system, with a slight change, was adopted in the Ronbary tunnel in 1828. During the third, and beginning of the fourth decades of this century, railroads had hardly been introduced in Germany. In 1837, however, in the construction of the Oheron and Konigsdorf tunnels, there began to be a difference of opinion as to the system in use, and at the Konigsdorf tunnel, the German system proper may be said to have been inaugurated. Here two bottom headings were first driven, and on them the foundations were laid; and at certain distances these headings were connected by crosscuts; and through these crosscuts, segments of the invert were built. Then a top heading was driven, which was widened out, and the arch turned. Finally, the center core was removed, and the segments of the invert previously put in the crosscuts were connected. The successful completion of the tunnel gave a reputation to the German system, which subsequent events did not justify.

The leading feature of the system is the employment of the center core. It is claimed by the advocates of the center core system that, first, in hard ground it gives cheap working, as the core is readily removed by the front, two sides and top blasting surfaces presented, which will give four open faces, and, with cross-cuts, five; second, that on soft ground exerting pressure as the openings are small, there is not as much danger as in other systems where large faces are presented; third, that the use of a standing core serving as a temporary support to the roof props, saves much timber. There are many defects, however, in the system, which have caused its abandonment even in Germany in late tunnels.

Tucson, Arizona, is filled with miners and prospectors, who have been driven in by the proximity of the hostile Indians.

New Form of Balance-Bob.

The term "balance-bob" is generally applied to an assemblage of parts of a trussed-frame or lever, used in mining operations for the purpose of storing energy by the raising of a certain weight during one part of an engine stroke, so that it may be given out during the other part of the stroke and thus equalize in part or whole the two strokes of the engine; or, when the pump rods balance each other, as in the double rod system, it may be used to support a part of the weight of the pump rod at intervals so that their weight will not be increased beyond their tenacity or a safe working limit.

These balance-bobs have heretofore had the nose fitted with a pin projecting from the cast iron portion, and the side rods have been attached to this pin so that any severe or unequal strain would be brought directly upon the cast iron, and would tend to rupture it.

Wm. R. Eckart, the well known mechanical engineer of this city, who is probably the best posted man on this coast in mining machinery, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved construction of balance-bobs, in which the side rods at the bob-nose are connected directly with the end of the wrought iron tension braces of the bob, so that the stress of the side rods is transmitted directly to the weight box of the bob without submitting any of the cast portion to tensile or transverse strains. The lower ends of the side rods are connected with the pump-rod saddle plate by equalizing levers, so that any variation in the distance between the end pins of either side rod will not produce unequal strain upon the rods or other parts.

The horizontal beam and king-post of the bob may be wood or cast iron. These are secured to a central casting, which forms or carries the trunnions. Struts, usually of wood, extend from the top of the king-post to the ends of the horizontal beams, and wrought iron straps or tension braces extend from the bob-nose over the top of the king-post, so as to sustain the strain of the weight.

The straps are secured to the beams by means of bolts or ties, or any of the well known ways. Pins pass through the ends of these braces, and the side rods are fitted to the projecting ends of the pins. If these rods are in pairs, or if they are single, the ends of the braces are forked, and the pin extends across the fork. The side rods extend down alongside the pump rod, and are connected with opposite ends of the equalizing bars, which extend across upon each side of the pump rod beneath the saddle plates. This connection of the side rods and the equalizing levers may be made by means of cross levers, to the centers of which the side rods are connected. The ends of these cross levers are connected with the ends of the equalizing levers. The saddle plates extend some distance along the wooden pump rod, and are strongly clamped to it by bolts, which pass through holes in the plates just outside the pump rod.

This gives a firm connection without the necessity of weakening the pump rod by any holes or cuts. The enormous weight that must be sustained by the pump rods sometimes causes the saddle plates to slip unequally, or the boxes or pins at the bob-nose to wear unequally, when the whole strain would be thrown on one side or the other if the side rods were rigidly secured to the saddle plates, and breakages would occur. This difficulty is overcome by the use of the equalizing levers.

EXTRA EDITION.—We had intended to publish an edition of twenty-four pages this week, but some unavoidable delay in the engraving department has compelled us to defer it until next week. We shall then issue a double edition, devoted more especially to Arizona and its mines.

THE Silver State has entered on its twenty-second volume. This journal, though small in size, should be an example to many others, from the way it collects the mining news of the various districts in its locality. There is always something of interest to be found in its columns, and it presents very fair and terse statements about local mines. The mining interests of any region are always assisted materially by such publications.

ELEVEN miles north of La Porte, an Illinois company last year worked by machinery to a depth of 300 feet, under the superintendency of J. Lilly. The parties must have met with success, for they have started a tunnel, and are working it day and night. The tunnel is to be about 1,400 feet long. The company owns several gold mines in California, and numerous coal mines in Illinois.

English Investments in the Pacific Coast Mines—No. 2.

Prepared for the MINING AND SCIENTIFIC PRESS by H. DEGRUIT.

The Emma Fiasco—Early History of the Mine.

The next of these Anglo-American investments, taking them in the order of their occurrence, consists of the Emma purchase, a transaction that, because of its magnitude and the alleged unfair means by which it was consummated, has caused no little scandal on both sides of the Atlantic. This mine, which is situated in Little Cottonwood canyon, Utah Territory, was located in 1868, by two prospectors named Woodman and Chisholm. Being without means to do the necessary work upon it, they afterwards disposed of a one third interest in their location to James E. Lyon, who thereupon advanced them enough money for that purpose. During that and the following year, a fair prospect was developed, and about 100 tons of good ore were extracted from the mine. Being impressed with the idea that the property might prove valuable, Woodman and Chisholm sought to oust their partner by relocating the claim, under the pretext that the lode ran in a direction different from that described in the original location, taking advantage of Lyon's absence from the country to carry out their scheme, he having meantime left on a visit to New York. Returning and finding how he had been served, Lyon brought suit, and recovered the one third interest that had been so wrongfully wrested from him; William M. Stewart, then United States Senator from Nevada, being his leading counsel. This accounts for Stewart's connection with the early history of the mine.

Treasurer W. Park Appears upon the Scene.

While in New York, Lyon had in some manner become acquainted with Treasurer W. Park, formerly and for a long time a resident of San Francisco, to whom he made such representations concerning the Emma claim, as induced that gentleman, accompanied by General Baxter, to come out to Utah in the month of March, 1871, and make an examination of the property, with which he was so well pleased that he induced the owners to transfer it to him, with a view of disposing of it on the London market. Under this arrangement the owners got but little cash down, but were to receive a considerable sum contingent on a sale of the mine being effected. Having got possession of the mine, Mr. Park, who had the entire business in his own hands, proceeded to organize the "Emma Silver Mining Company of New York," giving out that large bodies of valuable ore had been developed in the mine and that a great deal of money had already been expended upon it, both of which statements were in a good part true.

Whether or not Mr. Park in these preliminary stages of the business, or at any time thereafter, was more or less honest than the average promoter of these speculative schemes, certain it is he had already earned the reputation of being an astute lawyer as well as a shrewd and successful financier. Bred to the bar in the State of Vermont, he came thence to the Pacific coast at an early day, bringing with him those frugal and thrifty habits for which the natives of the Green Mountain State are apt to be noted. He had, moreover, become somewhat conversant with mining affairs through his connection with various enterprises of that kind, having also held for a number of years the position of "Receiver" for the celebrated Fremont estate, in Mariposa county. While discharging the functions pertaining to that position, Mr. Park so completely absorbed the resources of the property as to gain for him among the creditors of the bankrupt concern the appellation of the "Great Exhausting Receiver."

However much Mr. Park may have overestimated or exaggerated the importance of the Emma mine in the spring of 1871, there is no denying that a great deal of work had previously been done upon the property, which at that time presented a very promising appearance. Before going to England Mr. Park had the mine examined and reported upon by Professor Silliman, who for this service received, it is said, the sum of \$5,000, with the promise of a much larger amount in case the property was sold. That Prof. Silliman's report was favorable it is needless to say—that it was extravagantly so is a point open to some question.

Hunting for Capital on English Preserves

Having engineered matters up to the point above designated, Mr. Park, accompanied by Senator Stewart, leaving New York in the summer of 1871, crossed over to London. Arrived in the great metropolis, our adventurer, armed with Prof. Silliman's report, backed as it was by good accounts constantly coming forward from the mine, experienced little trouble in getting the ear of the English investing public, and that he took care to facilitate by first securing the good offices of certain influential personages and promoters of speculative schemes, by interesting them in his project.

Among the most conspicuous of the parties so subsidized, was one Albert Grant, who, for services to be rendered, was promised a fee of £100,000, payment being made contingent on the successful floating of the property. This Albert Grant, known also as Baron Grant, he

having bought the title somewhere abroad, and, not being a member of the regular British peerage, had made himself notorious by originating and successfully carrying out in London, Paris, and elsewhere on the Continent, a number of schemes distinguished for their magnitude and boldness, some of them being as disreputable as bold; but having made money, and thus condoned his offenses, Mr. Park considered him a proper person to help carry out his plans, despite his former questionable methods and unsavory fame. Baron Grant, though his career was afterwards brought to a disastrous and ignominious close, was, at the time of Mr. Park's advent in London, living in that city in great style, a power on the stock exchange, and a magnate in the financial world. He was at the head of railway enterprises and other important movements, few men having greater influence in moneyed circles than he. For the furtherance of Mr. Park's purposes, this Baron was therefore a very available person. Gen. Robert C. Schenck, then American Minister at the Court of St. James, was persuaded to buy some of the shares of the company proposed to be organized, and of which he was afterwards made one of the Directors. Gen. Schenck always maintained that he bought these shares, 500 in number, with his own money, and in good faith, and that they were not donated to him by Mr. Park, as many supposed.

Besides Baron Grant, other London dignitaries and people of high position were induced to take a little stock in this new venture, Mr. Park, it is surmised, having placed a few shares where he supposed "they would do the most good." With this progress made,

The Emma Silver Mining Company (Limited)

Was organized in London, and its prospectus issued on the 9th day of November, 1871. The capital stock of the company was fixed at £1,000,000, divided into 50,000 shares of the par value of £20 per share. Of these shares one half was offered to be subscribed for by the public, the vendors of the mine retaining the other half. The property was taken on the report of Prof. Silliman, and such other sources of information as the purchasers considered reliable, they having failed to first procure any report to be made upon it by their own agents or experts, a very unwise course of procedure, certainly. Prof. Silliman, besides other favorable statements, represented that there were in the spring of 1871, when he made his report, 32,000 tons of good ore in sight in the mine, while between that date and the time when the property was sold the English investors were given to understand that such developments had been made as largely increased its value. They were assured that not less than £46,000 of net profits had accrued in the interim, aside from 2,800 tons of first-class ore, of the estimated value of £70,000, that had been shipped to England, and 8,000 tons of second-class ore, of the estimated value of £64,000, piled up at the mouth of the mine, which latter still contained reserves larger than represented by Prof. Silliman, with much more of similar import.

Thus the advertised shares offered the public were soon subscribed for, and the purchase money paid over to the vendors by the trustees appointed to receive and hold it till the property had been duly transferred to the company. This done, the transaction was consummated to the satisfaction of all parties concerned—both the buyers and the sellers congratulating themselves on having made a good bargain.

In Bonanza for a Year.

Starting out under auspices so favorable, the new enterprise prospered for a time beyond expectation. The mine turned out bullion freely and the profits were large, admitting of greater dividends being paid than had been counted upon. Within four months from the time the company came into possession of the property their shares had advanced from twenty to twenty-three pounds sterling, at which figure they were in such demand on the London market that the Board of Directors, the shareholders concurring, bought from the vendors the 25,000 shares which they had retained, paying the full market price for the same.

Meantime, some ugly rumors having gotten abroad in regard to the outlook of the mine, the company decided to send out an agent to inspect and report on the same. Mr. E. Brydges Williams, member of Parliament for London and one of the Board of Directors, having been selected as a suitable person to perform that service. As the result of Mr. Williams' mission, the faith of the shareholders in the mine was fully re-established, that gentleman having found it all and even more than the vendors had represented it to be, and even going so far as to venture the opinion that the property was honestly worth twice as much as the company had paid for it. This was in the early part of April, 1872. Late in the fall of that year Mr. George Anderson, also a member of Parliament for London and a Director of the company, paid the Emma mine a visit, and after a careful examination endorsed all that Mr. Williams and Prof. Silliman had said of it, paying at the same time a high tribute to the integrity and dis-

interestedness of Messrs. Park and Stewart.

Disappointment, Disaster, and Final Collapse.

During the first year of its existence, the Emma company disbursed to the shareholders the sum of \$195,000, paying monthly dividends, the last of which, six shillings per share, was paid on the second day of December, 1872. Presumably these dividends were paid from the net earnings of the mine, though there is a suspicion that Mr. Park, being desirous of sustaining the market, advanced the money to pay the last two made. Be that as it may, the company at the end of 1872 found themselves confronted by the astounding discovery that their stock of available ore was exhausted, everything in sight worth taking out having been extracted without any new ore bodies having been developed or much advanced exploration done in the mine. Prof. Silliman's 32,000 tons in sight had shrunk to 11,420 tons, the quantity raised during the year. About the quantity shipped to England, there had occurred such mistake that the 2,800 tons reported in the company's prospectus had, in like manner, shrunk to 1,800 tons; Mr. Park, unable to account for the discrepancy, having, at a cost of £28,000, made up the same out of his own pocket. The quantity of ore reported afloat also turned out strangely deficient. Shrinkage and collapse occurred everywhere, causing the expected next annual yield of the mine to dwindle from £700,000 to the insignificant sum above mentioned.

The company unable to weather the crises so precipitated in the condition of their affairs, a collapse ensued. The mine was shut down and the working force dismissed. Dividends were "declared" off. The shares of the company from twenty-three pounds dropped speedily to one tenth that amount and finally to zero, being no longer quoted on the Stock Exchange. Everybody was disappointed and everybody disgusted. Inquiry into the causes of these disasters being now in order, it was ascertained that the mine, prior to its being visited by Messrs. Williams and Anderson, had been "doctored" in the most outrageous manner, the process of fixing it up consisting in the exposed parts being cemented with rich ore, the work having been done so adroitly as to defy detection. To accept this, the theory of those gen-

condition to which it had been reduced through long neglect, the excavated ground caved in and the plant destroyed, having been several years since carried away by a snow slide, the work of rehabilitation has proceeded rather slowly. Nevertheless, much has been accomplished, both in the direction of restoring as well as further exploiting the property, which at the present time presents a very encouraging appearance. Although experts have heretofore been divided in their opinions as to the merits and future prospects of the mine, few who have had opportunities for forming a correct judgment on that point entertain now any doubt but what valuable ore bodies will at no great depth below present workings be developed, and the company be brought into bonanza once more. This is the belief of all the resident miners, confirmed by the opinion of Prof. J. H. Morton, of Salt Lake city, who, besides being familiar with the history of the mine, is thoroughly conversant with the ores, the formations and the vein system of the district, where he has spent much time examining and reporting on properties, projecting and supervising improvements and in the discharge of such other duties as pertain to the position of a first-class mining engineer. Being an educated geologist as well as an experienced practical miner, Prof. Morton's opinion should perhaps, in this particular case, be considered worth more than those of all the other experts who have expressed their views on the prospects of the Emma mine combined. That subsequent developments may make good the favorable opinions of Prof. Morton is the fervent desire of many who have no other interest in such result than seeing these English investors, who, as a body, have acted honorably throughout this business, saved from ultimate loss.

INVENTION FOR PROSPECTORS.—F. B. BROWN, of Denver, has invented an electric apparatus for detecting and locating minerals, which is said to be a wonderful instrument and a marvel of science. It is a small electrical machine, with small points at the ends of the positive and negative wires. These points being held near together and moved over a piece of mineralized rock give a constant succession of sparks when passed over mineral of any kind, but a barren

Notes from Eureka, Nevada.

[From Our Regular Correspondent.]

EDITORS PRESS:—The tributers are taking a great deal of ore out of the Jackson mine, and, to facilitate this work, the company will cut out a new station in the shaft, between the third and fourth levels, which are 160 feet apart. A new drift will also be run from this station, by which it is thought that the continuation of the old ore bodies between the third and fourth levels will be found.

At the Albion Mine.

Three or four new prospect drifts have been started. The work is being done on contract. Several men are at work in the old chambers taking out ore. When a sufficient quantity is extracted to justify it, the furnaces will be started up. It is thought that they can be run successfully, notwithstanding past difficulties. At any rate, it will be cheaper to smelt the Albion ore at the company's furnaces at present, than to haul it to any other, as there is a large amount of charcoal and general supplies on hand. To haul these to any other furnace would be very expensive, added to which there is a large supply of charcoal, which it would be necessary to resack. The shrinkage on the charcoal would probably be twenty per cent., a loss of itself amounting to \$6,000 or \$8,000.

At the Eureka Con.

The Locan shaft has been sunk an additional 15 feet. During the few days that the water was pumped from the bottom of the Locan shaft to the surface, only a slight decrease was observable, but it is said that some of the drifts in the Richmond mine that had been under water for several years became perfectly dry. A few days ago Mr. Read commenced pumping the water up to the drain drift, which is 840 feet from the surface, since which it has been handled with ease, and there has been no obstacle in the way of the miners, who have been kept steadily at their work, sinking without interruption. I am told that the drifts in the Richmond mine, above mentioned, are again under water, and have been so since the Eureka Con. Co. have resumed the drainage through the 840 drift.

Judging from this, it will pay the Richmond Co. to join the Eureka Con. Co. in the expense of pumping, and in the event of their doing so, they might be enabled to drain both mines at a slight additional cost.

I am reliably informed that a very important movement is to take place here shortly in reference to

The Slag Dumps

At one or more of our furnaces, not to be made public, however, until all the arrangements are completed, but which, if successful, will certainly work a revolution in our district, as it will solve the problem of

smelting very lowgrade ores. This, added to the plan contemplated for working dry ores by lixiviation process, particularly those from the mines on the quartz belt of Adam's Hill, will doubtless be the means of bringing into renewed activity every mine in Eureka district, from the most extensively operated down to the smallest prospect.

The Richmond Company

Have reason to congratulate themselves on the bonanza that they are at present, and for several weeks past, have been uncovering in the slag pile at their own furnaces, the accretions in which are still proving immensely profitable, and the successful working of the same is due to the present intelligent management. To Mr. L. W. Davis, under Mr. Edward Probert, the general manager, is due the credit for a knowledge of the science of smelting superior to that of any of their predecessors. M. H. JOSEPH.

THE SILVER BELT MINE, in Big Bug district, is the property of D. C. Thorne, W. W. Hutchison and Mr. Symes, of this county, who have stuck to the Belt through evil and good report. Four months ago, when work was started anew, the company owed \$31,000, almost every dollar of which has been paid by profits from the mine, which is to-day the best little mine in America. A few miners take out daily three and one half tons of ore, worth at least \$203,000. This ore is packed on mules a distance of about eight miles to the Howell smelter. We believe Mr. Thorne's partners will accord him the credit of having been the "bravest" among them, for, when at times the vein was looking delicate, they felt like taking a rest, when Thorne was just in the humor of "seeing more" of it.—*Courier*.

THE Walker Lake Bulletin says that the first clean-up of the Cat Creek mill was a financial success. This settles the question as to the future of Wild Cat canyon and Cat creek. There is plenty of rich ore in sight in that country to keep several mills going, and the ledges are as numerous as in any part of the Wasatch range.

RENO now claims to have found a seven foot ledge of plumbago near its town limits.

DIFFERENT METHODS OF FRAMING MINE TIMBERS.

tle men in explanation of their mistakes, implies little fitness on their part for performing the task they had undertaken. It is hardly possible that they could have been imposed upon by a device so difficult of execution and yet so easy of detection. What seems more probable is that Messrs. Williams and Anderson, not having much experience as viewers of mines, were by their guides made to believe that much of the barren rock they saw was really rich ore.

Seeking Legal Redress and the Result.

Believing that they had been swindled by Mr. Park and his associates, the English directors instituted suits against these parties to recover the money paid for the mine. While these legal proceedings failed of that end, Mr. Park, who under foreclosure of mortgage finally came into possession of the property, voluntarily restored the same to the English company, under an arrangement that evinced on his part a willingness to act fairly, and even a desire to do right, and which, having been acquiesced in by the Board of Directors, afterwards met with the approval of most of the shareholders.

Under this arrangement, which was effected in 1880, a new company was formed with a nominal capital of £700,000, divided into 70,000 shares, 50,000 of which go to the original shareholders, the balance being apportioned among the debenture holders and vendors; a portion to be applied also in liquidation of indebtedness. Preference debentures receive £9,163 cash; ordinary £28,000 cash, and £52,820 in fully paid up shares. Of the remaining shares 11,000 go to Mr. Park and the vendors; 1,218 are to be used for general purposes, Mr. Park, subscribing for 2,500 shares, one half payable at once and the balance as required; the proceeds to be used as working capital. The entire property, with clear title, is conveyed to the new company, the old being liquidated. All legal proceedings are dismissed and mutual releases given to the company, the American defendants and Baron Grant.

The Re-constructed Emma.

The arrangement above described having been completed, work was soon after resumed on this much mismanaged, somewhat maligned and altogether unfortunate property, very little having been done upon it during the preceding seven or eight years. Owing to the wretched

rock does not affect it. If the ore extends through the rock continuously the machine will show it by holding the points on opposite sides of the rock. It will show whether the rock carries mineral or not, and also the comparative quality of ore. If one pole is placed in contact with ore in any mine and the other pole applied to a supposed extension of the vein it will show at once whether it is the extension or not. What is called static electricity is used, and the theory is based on the conductivity of metals for electricity. Copper and gold give distinct flames; copper, a greenish flame and gold a purple, while silver, lead, iron, etc., are white. This machine will prove of great value to prospectors, as they can test any float rock or specimen and tell in a minute whether it carries mineral, and whether much or little. The machines can be carried on the back, like a knapsack.—*Eureka Sentinel*.

Mine Timbering—No 8.

In the last number of the PRESS we gave some drawings showing several forms of timbering adopted in French coal mines. They have quite a variety of ways of working their timber, many of them devised particularly to economize the article which is scarce there. On this page are shown several of the methods of framing adopted. These are such as are in use in several parts of the world, as well. By referring to previous articles in this series, the difference between these systems and ours in use on this coast will be seen. The method of framing is so plainly shown in the engraving, that no detailed description is necessary.

A HOT PLACE.—Work is still progressing in the southeast drift on the 2,500 level of the Con. Virginia, but a good deal of water is coming in, and the drift is fearfully hot—almost seals the hair off the heads of the miners. None of the men working in that drift hanker after Russian baths. Their thoughts are of the ice fields of Alaska.—*Virginia Enterprise*.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 0x10 to 18x60. This latter size furnished J. R. Haggin for Olan and Old Abo Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jics, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Cal., 4,760 feet long; Mary Murphy mine, Cal., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 0x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and reliable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weighs 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to our address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free Circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 252 Market St., S. F. Elevator, 12 Front St.

BOONE & MILLER, Attorneys & Counsellors-at-Law

Rooms 7, 8 and 9.

No. 320 California Street, S. F.,

(Over Wells, Fargo & Co.'s Bank.)

Special Attention Paid to Patent Law.

N. B.—Mr. J. L. Boone, of the above firm, has been connected with the patent business for over 15 years, and devotes himself almost exclusively to patent litigation and related branches.

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplusage. Contains Dr. Raymond's Glossary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commission's Codification, and gives many and improved forms. Price—Full law binding, extra paper, 650 pages, \$5.00. For Sale by DEWEY & CO., San Francisco.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address, ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 26, 1883,

Mr. A. B. Paul:—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quicksilver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which glides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them. B. C. McLANE, Superintendent Indian Spring Drift Mine.

WHITALL, TATUM & CO.,

NEW YORK. PHILADELPHIA.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

BOAT DETACHING APPARATUS.—Thomas H. Sellers, Vallejo. No. 275,529. Dated April 10, 1883. This is intended to be applied not only to detaching boats when they are to be launched from vessels, but for again re-attaching them to the falls when they are to be hoisted to the davits. It consists of a horizontal shaft turning in boxes in the bottom of the boat, and having its ends enlarged with longitudinal slots, which extend to the center line of the shaft, so as to admit the free ends of bolts which have their opposite ends hinged in line with the shaft. Suspending links are hooked upon these bolts and connected with the tackle, and when the shaft is turned by a lever until the slots are upward, the free ends of the bolts are drawn out and allow the links to slip from them so the boat is free to fall. Each boat is provided with two sets of links, so the second set may be connected with the bolts, and be ready to connect with the boat when it is to be taken up again.

ARITHMETICAL CHART.—James B. Finch, San Jose. No. 275,475. Dated April 10, 1883. This is an arithmetical or number chart for purposes of instruction. It consists of a sheet having certain figures written in lines across it, with intervening signs for multiplication, division, addition or subtraction, and in combination with this sheet of slips having numbers pointed in a single vertical line upon each. The large sheet is fixed in a frame having slots at one side into which the slips are placed, and they may be moved up or down, so as to produce, with the figures upon the large sheet, new combinations or examples. The invention is intended to provide a simple arrangement of numbers, with the proper intervening signs, to give a number of different examples, and with these series of examples are employed slips having numbers arranged vertically, so that by moving a slip up or down, the examples may be changed.

SIPHONS.—Chas. E. Sherman, S. F. No. 275,530. Dated April 10, 1883. The invention relates to an improvement in siphons, by which they may be effectually kept clear of air, which will in time accumulate in the upper part of an ordinary siphon, and, if not removed, will stop the flow through the apparatus. It consists in the combination with the pipes of a siphon of a second discharge pipe and chamber, into which the upper ends of the pipes open independently, so that the interior of the chamber is also connected with the pipes, and any air which may have accumulated in this chamber will be forced into the discharge pipe, which acts as an air pump.

WINDOW BLIND.—Joseph Williams, San Jose. No. 275,537. Dated April 10, 1883. The blind consists of a number of independent parallel strips, pivoted above and below to peculiar guides which are pivoted to the window frames. The strips are so arranged that when the guides are horizontal said strips are extended so as to cover the window; but when the guides are raised to a vertical position the strips fold on one another and lie in a narrow compass at the sills of the window frame. The object is to provide an effective window blind; easy to open and close, and little liable to become disarranged.

TWO-WHEELED VEHICLE.—Willis O'Brien, S. F. No. 275,512. Dated April 10, 1883. The object of this invention is to render a two-wheeled vehicle an easy riding conveyance by relieving the body of the jogging motion of the horse. The improvements consist in a peculiar spring connection for the front of the body to limit and ease its play, and in a novel attachment of the whiffletree, whereby the freedom of the shafts, and the consequent independence of the body, may operate to the best effect.

REMEDY FOR AGUE.—Chas. L. Robinson, S. F. No. 275,524. Dated April 10, 1883. This compound is good as medicine in cases of fever and ague. It is to be taken internally. The peculiar ingredients used in the compound are patented in this connection.

A Mineral Exposition.

A short time since we published an account of a meeting of citizens at the State Mining Bureau to consult on the question of making a free exposition of the mineral and material resources of the Pacific coast. The coming summer will afford a great opportunity for the display of our mineral resources, as many strangers will be here.

A committee was appointed, consisting of the following gentlemen: Melville Atwood, L. L. Bullock, W. M. Bunker, Wm. T. Coleman, James V. Coleman, C. O'Connor, J. Z. Davis, John Daggett, Warren B. Ewer, S. Heydenfeldt, Jr., C. A. Hooper, Geo. T. Marye, Jr., W. H. Mills, Almarin B. Paul, I. M. Scott, J. R. Scupham, Chas. M. Tyler.

This committee has addressed a circular to the Board of Supervisors of each county in the State, setting forth the object of the Exposition and asking the county to be represented. The propositions are as follows:

First—It is proposed that the citizens of the city and county of San Francisco (and liberal minded citizens of the State who may so desire) raise all the funds required to project and carry out a Free Pacific Coast Mineral Exposition, and make the display one of unequalled attraction and interest to all who may visit the city.

Second—That the respective counties, and the citizens thereof, be earnestly solicited to contribute the sum of \$100 for each county, by appropriation or by private subscription, which may be sent to Lloyd Tevis, Esq., Treasurer of this Citizens' Exposition Committee, to go into what may be styled "The County Case Fund of the State Mining Bureau and Museum," to provide neat and uniform cases which will bear the names of the respective counties so contributing.

It is also most earnestly requested that immediate measures be taken by the respective boards to solicit specimens which may be sent by express, free, directed to the State Mining Bureau, with names of donors, which will appear on printed display cards in the respective county cases. Many relics, fossils, etc., will, no doubt, be sent which cannot go in cases, and for these a county space will be assigned by the committee.

When you feel out of sorts, have the blues, melancholy, etc., it must be indigestion that ails you. Brown's Iron Bitters cures it.

EXCELSIOR POWDER.—Attention is called to an advertisement of the Excelsior Powder Co. in another column. The company has been thoroughly reorganized and intend now to manufacture on a larger scale than heretofore. The powder has been on the market some little time, and is well known among mining men. It is represented as being not only very strong, but emits no disagreeable fumes or gases.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

"DUNCAN" ROCK DRILL!

FOR MINES, QUARRIES, ETC.

J. CUYAS, Agent,

10 Park Place, New York.

News in Brief.

THE Marquis of Lorne will probably succeed the Marquis of Ripon as Viceroy of India.

At Castle Garden, in one day this week, 4,469 immigrants landed from six foreign steamships.

THE railroad company is fairly at work extending the California and Oregon railroad northward.

THE Saratoga paper mills were burned Sunday night. Loss, \$40,000; insurance, \$18,000. The stock destroyed was principally straw paper.

CABBAGES continue to arrive from Germany, although a duty of ten cents is collected, and turnips are brought from Russia.—*New York Tribune.*

ABOUT 1,200 persons have contributed from \$175,000 to \$200,000 for the development of the Keeley motor, and the process of development is not yet finished.

THREE ore teamsters were fired on by Apaches in the Santa Rita mountains on the 13th inst., and two killed, one escaping. One of the men killed was named Thornburg. The Indians took the teams.

MANITOBA has entered a protest against the action of the Dominion Government looking to an increase in the duty on agricultural implements from the United States.

THE Boston *Advertiser* thinks the time is near at hand when the Pacific Coast will be able to compete successfully with the South or the entire country in the canned fruit trade.

DURING the first nine months of the current fiscal year, the internal revenue receipts were \$108,825,798, an increase of \$251,398 over the corresponding period last fiscal year.

GEN. CROOK does not believe the Indians can be successfully fought with regular troops, and will, therefore, employ Indian scouts, to which the Mexican authorities have assented, and will permit Cook's scouts to cross the borders in pursuit of the hostiles.

THE Mexican Central railroad company has signed a contract with the government consolidating all concessions made to the company since September, 1881. The first train from Washington at Mexico is expected next spring. It will be made a great festivity.

A WARDEN of the Cook county, Ill., hospital is made to say that one Chaffee, the County Undertaker, sells seventy-five per cent of the bodies to the medical colleges in Chicago and other cities, and that his revenue from this source has exceeded \$6,000 annually.

THE New Orleans *Picayune* reckons up a total of \$393,500,000 profit to American builders of Mexican railroads through Government subsidies, and suggests that the Republic is being practically sold out to "New York and Boston millionaires."

JAY GOULD, it is said, has declared his intention to retire from active business life on the completion of his steam yacht, *Atlanta*, built for his projected tour around the world. His son, George G. Gould, a young man of twenty-three years, is to take his place as a speculator. Gould is forty-seven years old, and his wealth is estimated at \$100,000,000.

THE information filed in the Superior Court of Colusa, charging Huron Miller with the murder of Dr. H. J. Glenn, was, on motion of Jackson Hatch, attorney for Miller, set aside. The ground was that Miller had not been legally examined and committed by a magistrate. Miller was discharged, but was immediately re-arrested and his examination set for Saturday, April 28th.

THE *Chico Record* of the 14th says: The land about Vina, which is nearly all owned by ex-Governor Leland Stanford, is fast settling up with a thrifty class of people from the East. Yesterday afternoon a carload of eastern immigrants passed through Chico to locate at this place, and two more carloads will pass through this evening.

NERVOUSNESS, peevishness, and fretting, so often connected with overworked females' lives, is rapidly relieved by Brown's Iron Bitters.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutheford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiry concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

EXCELSIOR BLASTING POWDER.

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no raw, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-glycerine Powder, as safe to use and handle as any other Nitro-glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headaches or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY,

Room 9, No. 3 California St., San Francisco, Cal.

SEEK

health and avoid sickness. Instead of feeling tired and worn out, instead of aches and pains, wouldn't you rather feel fresh and strong?

You can continue feeling miserable and good for nothing, and no one but yourself can find fault, but if you are tired of that kind of life, you can change it if you choose.

How? By getting one bottle of BROWN'S IRON BITTERS, and taking it regularly according to directions.

Mansfield, Ohio, Nov. 26, 1881.

Gentlemen—I have suffered with pain in my side and back, and great soreness on my breast, with shooting pains all through my body, attended with great weakness, depression of spirits, and loss of appetite. I have taken several different medicines, and was treated by prominent physicians for my liver, kidneys, and spleen, but I got no relief. I thought I would try Brown's Iron Bitters; I have now taken one bottle and a half and am about well—pain in side and back all gone—soreness all out of my breast, and I have a good appetite, and am gaining in strength and flesh. It can justly be called the king of medicines.

JOHN K. ALLENDER.

BROWN'S IRON BITTERS is composed of Iron in soluble form; Cinchona the great tonic, together with other standard remedies, making a remarkable non-alcoholic tonic, which will cure Dyspepsia, Indigestion, Malaria, Weakness, and relieve all Lung and Kidney diseases.

THE ALBANY CYLINDER OIL

Has its globuls undisturbed, stands fire test of more than 500 degrees, is perfectly free from acids or oxygen, clogs with more tenacity to the metal, and better resists the great pressure and heat of steam than any other lubricant.

MINERS' HORSE-WHIM

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timber, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

Office—Room No. 29, Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

Buchanan Gold Mining and Milling Company.—Location of principal place of business, San Francisco, Cal.; location of works, Tulumne, Tulumne county, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the 3th day of March, 1883, an Assessment (No. 2) of Five (5) Cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, room 3, No. 121 Post Street, San Francisco. Any stock upon which this Assessment shall remain unpaid on the 2d day of May, 1883, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on FRIDAY, June 1, 1883, to pay the delinquent Assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, F. J. SULLIVAN, Secretary.

OFFICE—Room 3, 121 Post Street, San Francisco, Cal.

ASSESSMENT NOTICE.

Seaton Gold Mining Company.—Location of principal place of business, San Francisco, California; location of works, Drytown, Amador county, Cal. Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of April, 1883, an assessment (No. 2) of seven and one-half cents (7½) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, A. Warner, at his office, No. 224 Kearny Street, room 2, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1883, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 5th day of June, 1883, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, A. MARTIN, Secretary.

OFFICE—Room 6, 523 California Street, San Francisco, California.

NOTICE TO CONTRACTORS.

Sealed proposals will be received by the Brandy City Mining Company until May 1, 1883, to run a bedrock tunnel to its mining lands, situated at Brandy City, Sierra County, Cal., near the town of Camptonville, Yuba County. Said Tunnel to be about 3,000 feet long, 6 feet wide and 8 feet high, with a grade of 5 inches to every 12 feet. Water Power furnished. Responsible parties only need apply. Privilege reserved to reject any and all bids. For further particulars inquire of

Improved Form of HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above cut of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "backing," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

JOSHUA HENDY MACHINE WORKS,

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec 22, 1874; Sept 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Copper Smelting Plant.

The illustration on this page represents the general form of construction of the Pacific copper smelting plants now in so much favor, and in use in many parts of the country. This arrangement of the machinery has been adopted after much study, with a view to construct the works so that the ore may require the least amount of handling in the course of the treatment of smelting, and also place the mechanical appliances in such relation to each other, that no more space will be required than is absolutely necessary, and at the same time have sufficient room for convenience. As will be seen the building is placed at the foot of the hill, and is divided into three floors.

The smelter is located upon the lower or ground floor. The ore, after passing through the crusher on the upper floor, is dropped down on to the middle or charging floor, when it is put into the smelter through an opening in the casing of the upper part of the smelter.

The plant, as shown, is intended for a Pacific copper smelter, having a capacity of handling thirty tons of ore a day. The manner of smelting the ore varies according to its character and the fuel employed. Ordinary carbonate or oxide ores require from twenty-five to thirty bushels of charcoal per ton, or from ten to fifteen per cent. of coke. Ores containing sulphur, arsenic, and antimony, should have their bases driven off before smelting. This can be done either by roasting in heaps or in a furnace made for this purpose. Ores carrying gold or silver can be worked to better advantage by converting the whole product into matte.

The construction of the smelter, which is, of course, the most important part of the entire machinery, is as follows: The body consists of a water jacket, which rests upon a heavy plate supported by four columns, the whole being placed upon a foundation plate. At the front of the furnace is placed a hulsion spout, and a slag spout is formed at one side near the bottom of the jacket. Above the spout is a wind box having suitable tuyeres for directing the blast to every part of the charge, which is received from the blower through a wind pipe at the rear of the smelter. The tuyeres, being entirely within the water space, are wholly protected from action of the heat, and consequently, never burn out or become a cause of trouble. Peep holes, with removable cap and mica covering, are arranged opposite each one, so the processes going on inside the furnace can be constantly observed.

The crucible is formed on a bottom, hinged to the plate, that can be instantly dropped when any obstruction occurs, or for access to the interior when repairs are necessary. A peculiar feature in the construction of the water jacket is the formation of circulating plates which create a rapid circulation of the water.

This device, by leaving no spot within the water space where the water is not in constant and rapid motion, causes the heat to be evenly distributed throughout the entire jacket, and thus prevents unequal expansion and contraction, and consequent leaky joints. The motion of the water also prevents any scale or sediment from depositing on the surfaces, and in this respect is of great advantage where the water used is highly mineralized. Great economy in the use of water is also attained by this device, as all the water introduced into the jacket is brought in contact with the heated surfaces, and none escapes the overflow without having absorbed all the heat possible. In many local-

ities where water is scarce, this point is one of much importance. Experience has shown this to be the most valuable improvement ever made in water-jacket smelters, adding at least two or three times to the effective wear and service of the jacket, besides saving in loss of time and cost of repair.

The smelters are made of ten, twenty and thirty tons daily capacity, the larger size being always recommended as the most desirable when the ore development will warrant, as it can be run more economically, both as regards fuel and attendance, than the smaller.

This size (thirty ton) water jacket requires about 25,000 gallons of water per day of twenty-four hours, when allowed to run to waste. When water is scarce it can be run into a reservoir and pumped into cooling tanks, requiring in this way only about 3,000 gallons. The blast for the smelter is furnished by a No. 4½ Baker blower. The breaker and blower are operated by separate engines, a ten-horse power engine required for the breaker, and that for the blower having a capacity of twelve-horse power. To complete the plant, a thirty-horse power tubular boiler, and a steam pump to feed same are provided.

This style of a smelting plant is so economically arranged as to warrant the erection of a

smelter upon any copper property carrying ore running as low as five per cent to eight per cent, circumstances being favorable as regards fuel and transportation. The extensive reputation which the Pacific copper smelter has attained certainly reflects much credit upon the manufacturers. Messrs. Rankin, Brayton & Co. report that they have now in hand orders for these smelters for Australia, South America and Mexico, besides a large number for various localities in this country.

Tucson Notes.

Our Arizona correspondent, B. W. Crowell, sends us the following notes from Tucson: "The Blue Jay mines are progressing with the work favorably. B. F. Carnes is President, Mr.

Mines near Johnson, Arizona.

Mr. J. G. Parke, Deputy U. S. Mineral Surveyor, kindly furnishes us with a few items about the region around Johnson, the newly laid-out town twenty-seven miles north from Tombstone, and seven miles from the Dragoon railroad station. The best and nearest mine to the town is the Peabody. There are now being erected two smelters of thirty tons capacity each. New hoisting works are also going up. Water is being brought in pipes from Russell, which will be ample for smelters, town, and all local purposes.

The "Old Mexican," now the Dreadnaught, Copper King, and Saratoga, are all being worked.

The Peabody is worked by Kansas City capitalists—Messrs. Underwood and Clark—under the able management of George J. Johnson. The roads are good, and there is plenty of wood as well as water in the neighboring mountains. They are working forty to fifty men in their different mines. The country around is considered a favorable one for prospecting. The Peabody Co. has now a large body of high grade ore exposed. In some of their chambers it is said to be forty to fifty feet wide in pay ore.

In the Chiricahua mountains, a range east of Sulphur Spring valley, and running on down to the Mexican line, where it becomes broken, there are many good mines. The Dunn mine, but little developed, has a small smelter. They are now negotia-

ting a sale with capital from Youngstown, Ohio. The Josephine is a partially developed mine on the same range, with a large body of high grade smelting ores of galena and carbonates. The great detriment and retarding influence has been the occasional Indian outbreaks, being on the trail from Sonora.

UTILIZATION OF PYRITES REFUSE FOR STEEL MAKING.—Experiments are now making at the Terrebonne works for utilizing the residue of iron pyrites. Briquettes are made with the conglomerated with hydraulic lime; and, by simple exposure to the atmosphere, an ore is obtained which is said to yield pig excellent for steel making purposes. The sulphur is believed to be completely counteracted by the lime, and there is no phosphorus. The company has large hauls of pyrites refuse that it has hitherto been unable to utilize.

EIGHT miners have been arrested and taken to Eureka to answer for having tarred, feathered and ridden on a rail A. P. Hodgdon, whom they believed had made an attempt to destroy Geddes and Bertrand's hoisting works, at Secret Canyon, although he had been acquitted of the charge in a jury trial.

GENERAL ARRANGEMENT OF PLANT FOR COPPER SMELTING.

Latest Instructions to Settlers upon the Public Domain.

A Digest of all the Settlement Laws and the Rulings Thereon.

The following circular of instructions relative to entries under the homestead, pre-emption, and timber culture laws, issued by the Commissioner of the General Land Office, under date of March 15, 1883, and addressed to Land Registers and Receivers, is valuable as embodying the provisions of all the land laws, and the construction placed upon them by the General Land Commissioner:

GENTLEMEN:—You are instructed to deliver to applicants for land under the homestead, pre-emption, or timber culture acts, a copy of this circular, and to especially call the attention of the applicant to the requirements of the law under which the application is made.

Residence of Applicant.

1. The applicant must in every case state in his application his place of actual residence, and the post office address to which notice of contest or other proceedings relative to his entry shall be sent.

Second Filings and Entries.

2. A party making a legal filing or entry under any one of the foregoing Acts exhausts his right under that Act, and cannot thereafter make another filing or entry under said Act.

Alterations in Applications.

3. Applications to amend filings or entries should be filed with the Register and Receiver, and be by them transmitted for the consideration of this office. Registers and Receivers will not change an entry or filing so as to describe another tract, or change a date after the same has been recorded.

Relinquishments.

4. Entries and filings made for the purpose of holding the land for speculation and the sale of relinquishments are illegal and fraudulent, and every effort in the power of the Government will be exerted to prevent such frauds and to detect and punish the perpetrators.

5. The first section of the Act of May 14, 1880, provides that when a pre-emption, homestead, or timber culture claimant shall file a written relinquishment of his claim in the land office, the land covered by such claim shall be held as open to settlement and entry without further action on the part of the Commissioner of the General Land Office.

6. This act refers to bona fide relinquishments of bona fide entries. An entry fraudulent in its inception is not an entry capable of being relinquished. It is an entry to be canceled upon a proper showing of the facts and circumstances of the case, whereupon the land will become subject to proper entry by the first legal applicant.

7. Purchasers of relinquishments of fraudulent filings or entries should understand that they purchase at their own risk so far as the United States is concerned, and must seek their own remedies under local laws against those who, by imposing such relinquishments upon them, have obtained their money without valuable consideration.

Settlers on Unsurveyed Lands.

8. Homestead and pre-emption settlers on unsurveyed lands are allowed three months after the filing of the township plat of survey within which to put their claim on record. Accordingly no party will be permitted to make final proof in any case until after the expiration of said three months.

The Homestead Laws

9. Homestead entries can be made for not more than one-quarter section, or 160 acres of land.

10. The Land Office fees and commissions, payable when application is made, are as follows:

In Alabama, Arkansas, Dakota, Florida, Iowa, Kansas, Louisiana, Michigan, Minnesota, Missouri and Nebraska—

LAND AT \$2.50 PER ACRE:

For 160 acres.....	\$18 00
" 80 ".....	9 00
" 40 ".....	7 00

LAND AT \$1.25 PER ACRE:

For 160 acres.....	\$14 00
" 80 ".....	7 00
" 40 ".....	6 00

In Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming—

LAND AT \$2.50 PER ACRE:

For 160 acres.....	\$22 00
" 80 ".....	11 00
" 40 ".....	8 00

LAND AT \$1.25 PER ACRE:

For 160 acres.....	\$16 00
" 80 ".....	8 00
" 40 ".....	6 50

11. When a person desires to enter a tract of land upon which he has not established a residence and made improvements, he must appear personally at the district land office and present his application, and must make the required affidavits before the register and receiver.

12. He must then establish his actual residence (in a house) upon the land within six months from date of entry, and must reside upon the land continuously for the period prescribed by law.

12. In the case of a single person, the actual residence must be established within the same

time, and must be continuously and actually maintained for the same period.

14. The homestead affidavit can be made before the clerk of the county court only in cases when the family of the applicant, or some member thereof, is actually residing on the land which he desires to enter, and on which he has made bona fide improvement and settlement, and when he is prevented by reason of distance, bodily infirmity, or other good cause, from personal attendance at the district land office.

15. In such case, the applicant must state in a supplemental affidavit the facts of such settlement, improvement and residence, what acts of settlement have been performed, and when made, the nature, extent and value of the improvements, what member or members of his family are residing on the land, and the length of time such residence has been maintained, and the cause, specifically, why the applicant can not appear at the local office.

16. A false oath taken before the clerk of the county is perjury, the same as if taken before the register or recorder.

17. The period of actual inhabitation, improvement and cultivation, required under the homestead law is five years.

18. In case of the death of a homestead party before making final proof the widow succeeds on the homestead right.

19. In case of the death of both father and mother, the right and fee inure to the minor children, if any.

20. The homestead right cannot be devised away from the widow or minor children.

Soldier's Homestead.

21. A Union soldier or sailor of the late war is entitled to a deduction from five years of the length of time (not exceeding four years) of his military service. But the soldier (or his widow, as the case may be,) must actually reside on the land at least one year before final proof can be made.

22. In case of the death of the soldier, and the death or re-marriage of the widow, the minor children of the soldier, by a duly appointed guardian, are entitled to the privileges of the father.

23. Neither the guardian nor the minor children are required to reside on the land, but the same must be cultivated and improved for the period of time during which the father would have been required to reside upon the tract.

24. The soldier may file a declaratory statement for a tract of land which he intends to enter under the homestead laws. The fee is two dollars, except in the Pacific States and Territories, where the fee is three dollars.

25. This statement may be filed either personally or by an agent, and the soldier thereafter is allowed six months within which to make his entry and commence his settlement and improvement.

26. The entry can be made only by the soldier in person at the local land office, and he must actually make his entry and commence his settlement and improvement within six months after his filing, and must continue to reside on the land and cultivate it for such period as, added to his military service, will make five years. But he must actually reside on the land at least one year, whatever may have been the period of his military service.

27. Entries cannot be made for a soldier by an agent or attorney.

28. After a declaratory statement has been filed, whether by an agent or otherwise, the soldier cannot file again. His rights are exhausted by the first filing, and if he does not within six months make his personal entry at the Land Office, and commence his settlement and improvements as required by law, he obtains no right to the land.

29. A soldier's homestead declaratory statement for a tract of land does not prevent anybody else from making an entry of the same land, subject to such right as the soldier may require by virtue of actual residence on the land, and full compliance with law. If the soldier does not establish his residence on the tract as required, the next comer may take the land.

30. Soldiers are not entitled to land, nor to bounty land warrants for their military service in the late war, nor can titles to land be obtained for them by agents or attorneys. All representations to the contrary are false, and soldiers and sailors are warned against imposition by parties who offer to locate land for them, or to sell their rights.

Commuted Homesteads.

31. Homestead entries can be commuted to cash only after actual inhabitation of the land by the homestead party, and his improvement and cultivation of it for a period of not less than six months.

32. A person who commutes a homestead entry can not move from the tract and settle upon other public lands in the same State or Territory as a pre-emptor.

33. Proof of settlement and cultivation for the prescribed period is to be made in the same manner as in pre-emption cases.

34. A person commencing a homestead entry when he has not actually resided upon the land and improved and cultivated it as required by law, forfeits all right to the land and to the purchase money paid, and, in addition thereto, renders himself liable to criminal prosecution.

35. A settler desiring to make final proof must file with the register of the proper land office a written notice, in the prescribed form, of his intention to do so, which notice will be published by the register in a newspaper, to be

by him designated as nearest the land, once a week for six weeks at the applicant's expense.

36. Applicants should commence to make their proof in sufficient time so that the same may be completed and filed in the local office within the statutory period of seven years from the date of entry.

37. The final affidavits and proof should be made before the register or receiver, but may be made before the judge, or in his absence, before the clerk of a court of record in the county and State, district or Territory, in which the land is situated. If in an unorganized county, the proof may be made in a similar manner in an adjacent county in the same State or Territory.

38. When proof is made before the county officers mentioned, the same must be transmitted by the judge or clerk of the court to the register and receiver, together with the same commissions and fees that the land officers would have been entitled to receive if the proof had been made by them and the testimony reduced to writing by them.

39. The land office commissions, payable at the time of making final proof, are as follows:

In Alabama, Arkansas, Dakota, Florida, Iowa, Kansas, Louisiana, Michigan, Minnesota, Mississippi, Missouri and Nebraska—

LAND AT \$2.50 PER ACRE:

For 160 acres.....	\$8 00
" 80 ".....	4 00
" 40 ".....	2 00

LAND AT \$1.25 PER ACRE:

For 160 acres.....	\$4 00
" 80 ".....	2 00
" 40 ".....	1 00

In Arizona, California, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming and Colorado—

LAND AT \$2.50 PER ACRE:

For 160 acres.....	\$12 00
" 80 ".....	6 00
" 40 ".....	3 00

LAND AT \$1.25 PER ACRE:

For 160 acres.....	\$6 00
" 80 ".....	3 00
" 40 ".....	1 50

40. The fees for reducing testimony to writing in making final proof are, in the former States, 15 cents, and, in the latter States and Territories, 22½ cents for each 100 words. No other land office fees than those stated in this circular are payable or allowable in homestead cases.

The Pre-emption Law.

41. The qualifications required of a pre-emptor are that he (or she) shall be a citizen of the United States (or have declared an intention to become such); over 21 years of age or the head of a family; an actual inhabitant of the tract claimed; and not be the proprietor of 320 acres of land in any State or Territory.

42. A person who has removed from land of his own to reside on public land in the same State or Territory, or who has previously exercised his pre-emption right, is not a qualified pre-emptor.

43. Lands included in any reservation, or within the limits of an incorporated town, or selected as the site for a city or town, or actually settled and occupied for purposes of trade and business and not for agriculture, or on which there are any known salines or minerals, are not subject to pre-emption.

44. If the land is surveyed, but has not been "offered," the declaratory statement must be filed within three months from date of settlement. If upon "offered" land, the filing must be made within thirty days.

45. If the land is unsurveyed at the time of settlement, the declaratory statement must be filed within three months after the date of filing the township plat in the local office.

46. Failure to file a declaratory statement within the time prescribed makes the land liable to the claim of any adverse settler who does file notice of his intention at the proper time.

47. The land office fee for filing a declaratory statement is \$2, except in the Pacific States and Territories, where the fee is \$3.

48. A pre-emption filing can be made only by an actual settler on the land. A filing without settlement is fraudulent and no rights are acquired thereby.

49. The existence of a pre-emption filing on a tract of land does not prevent another filing to be made of the same land, subject to any valid rights acquired by virtue of the former filing and actual settlement, if any.

50. On offered lands proof and payment must be made within twelve months from the date of settlement.

51. If the land is not offered, proof and payment must be made within thirty three months from date of settlement.

52. A failure to make proof and payment as prescribed by law, renders the land subject to appropriation by the first legal applicant.

53. The same requirements of actual inhabitation and improvement must be observed under the pre-emption law as under the homestead law.

54. Failure to inhabit and improve the land in good faith, as required by law, renders the claim subject to contest and the entry to investigation and cancellation.

55. Final proof in pre-emption cases must be made to the satisfaction of the register and receiver, whose decision, as in other cases, is subject to examination and review in this office.

56. Publication of notice to make proof is required as in the homestead cases.

57. The final affidavit must be made before

the register or receiver, or before the clerk of the court of record in the county and State or Territory where the land is situated.

58. The pre-emptor is required to make oath that he has not previously exercised his pre-emption right; that he is not the owner of 320 acres of land; that he has not settled upon and improved the same to sell on speculation, but in good faith to appropriate it to his own exclusive use; that he has not made any contract or agreement, directly or indirectly, in any way or manner, with any person whomsoever, by which the title he may acquire from the United States shall enure in whole or in part to the benefit of any person except himself.

59. Any person swearing falsely forfeits all rights to the land and to the purchase money paid, besides being liable to prosecution under the criminal laws of the United States.

The Timber Culture Act.

60. A timber culture applicant is required to make oath that his filing and entry is made for the cultivation of timber and for his own exclusive use and benefit; that he makes the application in good faith and not for the purpose of speculation, nor directly or indirectly for the use or benefit of any other person whomsoever; and that he intends to hold and cultivate the land and to wholly comply with the provisions of the act.

61. Claimants under the timber culture act will be held to a strict compliance with the terms and conditions of the law.

62. Not more than one quarter of any section can be entered under this act.

63. Where 160 acres are taken, at least five acres must be plowed within one year from date of entry. The following, or second year, said five acres must be actually cultivated to crop or otherwise, and another five acres must be plowed. The third year the first five acres must be planted to trees, tree seeds, or cuttings, and the second five acres actually cultivated to crop or otherwise. The fourth year the second five acres must be planted to trees, tree seeds, or cuttings, making, at the end of the fourth year, ten acres thus planted to trees.

64. Perfect good faith must be shown at all times by claimant. Trees must not only be planted, but they must be protected and cultivated in such manner as to promote their growth.

65. Final proof may be made at the expiration of eight years from date of entry. It must be shown that for the said eight years the trees have been planted, protected and cultivated as aforesaid; that not less than 2700 trees were planted on each of the ten acres, and that at the time of making proof there are growing at least 675 living thrifty trees to each acre.

66. Where less than one quarter section of land is entered, the same proportionate amount of plowing, planting, and cultivation of trees must be done as required in entries of 160 acres.

67. If the trees, seeds, or cuttings are destroyed in any one year they must be replanted. A party will not be released from a continued attempt to promote the actual growth of timber or forest trees. A failure in this respect will subject the entry to cancellation.

68. Only an applicant for the land under the timber culture or homestead laws can institute a contest under the third section of the Act of 1878.

69. Contestants have a preference right to thirty days after cancellation in which to make entry of the land.

70. The Government will at any period, upon proper application to contest, or upon its own information, investigate alleged fraudulent or illegal timber culture entries, or alleged failure to comply with the law after entry, and such entries will be canceled under sufficient proof either of illegality or failure to comply with the law.

71. The land office fee for an entry of more than 80 acres is \$14; 80 acres or less, \$9.

Cautions to Applicants.

Persons making filings or entries under the homestead, pre-emption, or timber culture acts, are cautioned that the laws authorize entries to be made only for the use and benefit of the party making the same, and that entries or filings are not allowed by law to be made for the benefit of others nor for speculation, but all entries must be made in good faith, and the requirements of the law must be honestly and faithfully complied with. Very respectfully,

N. C. McFARLAND, Commissioner.

The following is from the Revised Statutes of the United States:

Section 2240. The register or receiver is authorized, and it shall be his duty to administer any oath required by law or the instructions of the general land office, in connection with the entry or purchase of any tract of public lands; but he shall not charge or receive, directly or indirectly, any compensation for administering the oath.

Penalties.

Sec. 5392. Every person who having taken an oath before a competent tribunal, officer or person, in any case in which the law of the United States authorizes an oath to be administered, that he will testify, declare, depose, or certify truly, or that any written testimony, declaration, deposition or certificate by him subscribed is true, wilfully and contrary to such oath, states or subscribes any material matter which he does not believe to be true, is guilty of perjury, and shall be punished by a fine of not more than two thousand dollars, and by imprisonment at hard labor not more

(CONTINUED ON PAGE 286).

MECHANICAL PROGRESS.

Curious Ideas About Compression.

An English professor has recently written to one of the engineering journals in reference to the matter of compression or cushion in the steam engine cylinders. He sets forth his premises by saying that "Cushioning is supposed to save steam by filling the passages, ports and other necessary clearance so that this has not to be filled with fresh steam, which does no work in filling them." His second proposition is to the effect that "Cushioning is often supposed, by relieving the crank from the duty of stopping the piston, and so diminishing the pressure upon the crank pin and bearing, to diminish the friction." While his last is, "Cushioning is found by experience to be necessary in the case of all high speed engines to prevent the sudden shock attending the admission of steam." He then goes on to say that "if an engine, when running at its greatest speed, knocks or bumps in its bearings, it is a sign that it is insufficiently cushioned;" then he goes on to give a theoretical explanation, speaking further on of pumps, reversals, inertia, joints, etc. He then takes the ground that the steam with which the clearance is filled is not at all gain, and, finally, winds up by concluding that cushion should not be carried further than sufficient to prevent bumping.

This is very important information for engineers. Most any of them could figure out just how far cushioning should be carried to prevent bumping. They can probably tell us precisely the number of pounds at all the variations of speed with enormous as well as with small clearance, etc., but the real fact of the question is, cushioning or compression properly applied to any engine means economy. We all know that air, if compressed, is heated; hence, compression means heat, or a saving of heat. We all know that if we compress sufficiently to make five, ten, fifteen, or twenty pounds of compression, that we really fill the volume of the cylinder after the exhaust valve is closed, providing the piston and all the working parts are tight with the volume of steam that represents twenty pounds pressure per square inch, or whatever the pressure may be. This certainly relieves any little working that there may be in the cross-head, in the crank connection, or shackle bar, and certainly allows the piston and all these parts to cushion gently, instead of covering up without any cushion, and making the inevitable—in that case—"chug," which is one of the things that working engineers invariably dread. If we compress twenty pounds, it requires a less volume of directly admitted steam by a large percentage of that twenty pounds than it would if the twenty pounds were not there. This does not need to be guessed at,—a certain volume of steam is saved. The compression, if proper, saves in repairs on the engine, and makes it work longer and work better. There is no doubt that this cushioning costs something, but it brings more benefit than it costs, undoubtedly, hence there is no necessity for using theory or moonshine with regard to the theoretical value of cushioning or compression. True it is that some of our best engineers never use it, but when their work is carefully indicated upon the basis of proper compression, the engine always runs quietly and economically from the coal pile. Cushioning is of as much necessity, based on experience, in a low pressure engine running fifteen revolutions, as it is in the electric light engines running 380 revolutions. Cushioning is of no more necessity on a locomotive with six feet drivers, making a mile a minute, than it is on any slow moving engine. It may require a larger amount of compression, with a higher speed, for the velocity is greater, the momentum is more, and the cushioning must of necessity be more in amount, or more per square inch. The real effect is no more or no less. The cushioning will relieve what might otherwise be disagreeable in its general effects, by allowing the piston, and consequently all the parts connected with it, to bring up gently, with something to overcome their tendency to go further than their connections would allow them, after the entire amount of steam in front of the piston has been exhausted, and nothing left for it to cushion upon.

Men who have experimented with cushioning practically, invariably use it to a greater or less extent. Cushion does not mean steam lead; there is no necessity for opening your steam valve two inches before the piston gets at the extreme end of its stroke, in order to obtain cushion, that is not what we mean,—nor would we give an engine steam one third of the stroke off for the sake of showing the compression line. Give your steam at the proper place and compress by the exhaust valve. These professors are curious fellows. They will make you believe, if possible, that the world is square, and that a drop of water has the power of getting up and going off somewhere, but when you come to put their theories into practice they are not always found to be true.

So with compression: try it carefully; try it only with the indicator; make sure of your premises, and don't allow theory to enter into it, but put it to the actual test, and find out whether compression properly used does not benefit the coal pile, save the engineer trouble, make the machine do better work, last longer, and a man need not write "professor" after his

name to determine these facts for himself in his own engine-room, to the satisfaction of his employer.

PILE DRIVING BY DYNAMITE.—According to Austrian accounts, some interesting experiments were recently made in connection with the execution of some municipal works at Buda-Pesth. It appears that a number of piles already driven were required to stand a greater load than had originally been contemplated, and it was consequently necessary to test them and drive those that yielded still deeper. Bringing a pile-driving machine successfully over each pile for so small an amount of work would necessarily have entailed considerable expense, and it was consequently determined to try the effect of dynamite. For this purpose the piles were cut square, and a wrought iron plate fifteen inches in diameter and four and three eighths inches thick was placed on the top of each. In the center of this plate, and immediately over that of the pile, was placed a charge of dynamite in the form of a cake six inches in diameter and three fourth inch thick, and weighing about seventeen and one half ounces. The dynamite was wrapped in parchment paper and covered with clay and ignited, and the effect so produced was found to be equal to about five blows from a 1,475 pound monkey falling from a height of about nine feet ten inches. The iron plates, it is said resisted from twenty to twenty-four explosions.

A NOVEL WAY OF BREAKING METAL.—An effective method of breaking up considerable pieces of iron and steel has come into use as a substitute for the process of melting them by means of colossal air furnaces—namely, the application of the force which confined water experts in every direction upon the material in which it is enclosed. A round hole, two or three inches in diameter and ten or twelve inches deep, is bored into the mass to be split, the hole being then filled with water and closed by a tight-fitting steel cylinder, upon which a weight is allowed to fall from the usual height. In this way, a plate roll of some thirty inches diameter has been split into four or five parts, the pieces flying twenty or thirty feet. A single blow of an ordinary drop weight usually suffices to split off pieces of thirty to thirty-six inches in diameter. It being essential that the hole be hermetically closed, this is accomplished by hollowing out the base of the cylinder into a cup-shaped form, the edges of which are driven against the walls of the hole by the water in its endeavor to get past. A pin of good steel can be used several times in this operation.—*St. Louis Republic.*

TALL CHIMNEYS.—The necessity of having tall chimney shafts is undoubtedly becoming obviated. We know that they are dangerous, and all are agreed that they are hideous architecturally, while recent practical experiments go a long way to show that, after all, short chimneys are not only less dangerous and in better taste, but that they effect a great saving. A new oven, which is described by a correspondent of the Yorkshire Post, would appear to render high chimneys quite unnecessary. Any manufacturer can, it seems, put an oven up at his works, and get from every ton of slack he uses coke worth 7s., tar and ammonia worth 4s., and 14,000 feet of gas to generate steam. The coke, tar, and ammonia will, it is said, considerably more than pay for slack, labor, wear and tear, and interest on the cost of the ovens, so that he will, according to this, actually get his steam for less than nothing. The smoke and vapors are claimed by the process to be all turned into money, instead of being wasted through a high chimney.

DANGEROUS PRACTICES.—F. B. Allen, in the *Locomotive*, says: When a boiler gives signs of distress, by unusual leaking, or by other well-known indications, it must at once and with the least possible disturbance be put out of service until it can be thoroughly examined by a competent inspector and the nature of the defect determined. The average water tender puts a heavy feed on the boiler and gets a ladder with which he may climb up and watch the spread of the leak. In opening the flue doors in the setting, to afford him the necessary view, unwittingly, no doubt, he permits a stream of cold air to sweep the boiler bottom, which adds another important element to its destruction, and perhaps his own. We would as soon think of entering a power magazine with a lighted cigar, as to do either of these things at the time or under the circumstances we have described.—*United States Miller.*

THE GJERS' SOAKING PIT.—According to present reports, Mr. Gjers' soaking pit continues to give excellent results in Great Britain. At the West Cumberland Iron and Steel Works, Workington, where the process is in full swing, 2,572 ingots, weighing 2,391 tons, were recently put through 14 soaking pits, yielding 2,176 tons of rails and 77 tons of blooms. The rail mill worked 11 shifts. The ingots put through the soaking pits were clogged direct from them to eight-inch blooms; they were then reheated and rolled into rails. Three second-heating furnaces were used, and the mill work was done with one cogging and one finishing engine.

SCIENTIFIC PROGRESS.

Science in Soap Bubbles.

The soap bubble has now come within the reach of science. By means of those gauzy globes many beautiful and interesting experiments have been made at the Franklin Institute during a lecture by Mr. B. S. Holman, actuary of the Institute, on "Some Effects of Light and Sound." The instruments used were the Holman lantern microscope and the same gentleman's later invention, the phonoscope, which may be translated into "seeing sound." The former instrument consists of a metal box containing an oxyhydrogen light, which is thrown at any angle by condensing lenses upon the object to be magnified. This light is reflected off at another angle through the magnifying lens on a screen, where the object is displayed greatly magnified.

The phonoscope consists of a thin metal tube, on one end of which is a thin cap in which a hole one inch square is cut, and at the other end is a large mouthpiece, such as is used on speaking tubes. The soap bubble preparation is composed of oleate of soda and glycerine, and from it bubbles two feet in diameter and of exceeding brilliancy can be blown. Some of these have been kept forty-eight hours under glass. The lecturer dipped the small end of the phonoscope into a saucer filled with this preparation, which left a film across the square opening. The cone of light from the lantern was then thrown upon the film and reflected upon a screen through the magnifying lens, making the figure about two feet square.

The effect was beautiful. At first nothing but a gray surface was seen, then gleams of color appeared, and in a moment the whole square was a mass of a dazzling brilliancy which would have put to shame any kaleidoscope ever made. Every instant the beautiful picture changed; now a wonderful design in reds and yellows, looking like a tea-store chromo of an Italian sunset, then shifting to a swarm of peacocks' tails, or a pantomime transformation scene struck by lightning and as suddenly changing to a somber view in blue and purple, or a rainbow dancing a waltz. After showing several of these pictures, the lecturer proceeded to show the effects of sound upon the soap bubble. A couplet was sung into the phonograph, the mouthpiece of which was placed against the mouthpiece of the phonoscope, and the crank was turned. As the sound issued forth, a curious effect was produced upon the picture. Geometrical figures in black appeared upon it, small and distinct when the notes were high, large and less clearly cut when the notes were low. Around and among the black figures whirled the ever changing colors, red, blue, green, yellow, in all their varying shades, melting into one another too quickly for their blending to be followed by the eye. Human voices, also, sang to the soap bubble, and with equally enriens results. It is proposed to exhibit this experiment on a very large scale as soon as the new lantern microscope, now being made for the institution, is finished.—*Philadelphia Record.*

SUN EXPLOSIONS.—A great deal of wonder has from time to time been excited by the statements of astronomers concerning the enormous velocity with which the matter forming the protuberances, or fiery fountains, seen on the edge of the sun during periods of the great solar disturbance, is shot upward from the general level of the photosphere. This velocity amounts in some cases, to several hundred miles a second. Now M. Paye, the French astronomer, who has been looked upon by some as a little too obstinate in rejecting certain conclusions about the sun which most astronomers have accepted, comes forward to combat the general opinion in regard to the formation of solar protuberances. He does not admit that the glowing gas forming the protuberances is hurled forth from the sun at the rate of 300 or 400 miles a second, and undertakes to explain how astronomers have been deceived. According to him, the gas in question, having risen above the level of the photosphere, expands and cools to such a degree as to become invisible. But at intervals the intense solar radiation heats this gas so that it becomes visible again. The heating begins from beneath and extends swiftly upward, thus producing the appearance of matter shot forth from the sun with tremendous velocity. It is hardly probable that this ingenious hypothesis will be fully accepted. While it may explain some of the appearances which have been noticed, it will be difficult to convince those who study the sun with the spectroscopic that gaseous matter is not at times hurled forth from the solar orb with the tremendous velocity before mentioned.

VIBRATIONS PRODUCED BY RAILWAYS TRAINS. Prof. H. M. Paul has communicated some interesting notes on the effect of railway trains in transmitting vibrations through the ground. A box, holding mercury thickened by amalgamation with tin, was placed upon a heavy plank screwed to the top of a post sunk four and a half feet into the ground. An express train, passing at a distance of one third of a mile, set the surface of the mercury in confused vibration for two or three minutes. Other observations were made at stations at somewhat greater distances. The experimenter also found that a one-horse vehicle passing down a gravelled road 400 or 500 feet distant caused a temporary agitation of the mercury whenever the wheels struck a small stone.

THERMAL BELTS OF NORTH CAROLINA.—In a paper on this topic, recently read by Prof. J. W. Chickering, it was stated that the valley of the Little Tennessee river, in Macon county, is about 2,000 feet above tide. When the thermometer indicates a temperature of about 26° F., the frost extends about 300 feet in vertical height up the mountain sides, and there ceases, appearing again 400 feet higher. In the intervening belt the most delicate plants remain untouched. Following a tributary stream upward from the valley, one passes three mountain barriers and enters in succession three valleys, the highest of which is plateau-like, and 3,900 feet in altitude. The vernal zone appears in each valley, rising as the valleys rise, but somewhat less rapidly, so that in the highest it is only 100 feet above the plateau. In this frostless zone the Isabella grape not merely has ripened for twenty-six consecutive years, but is free from mildew, blight and rust. In Polk county a similar belt is said to skirt the Tryon mountain, extending from 1,200 to 2,200 feet above tide. This is untouched by frost until the latter part of December, and is usually free from snow, while the mountains above and the valleys below are covered. The peculiar stratification of the air indicated by these statements merits scientific investigation.

HOW LONG IT TAKES TO SMELL.—Various delicate experiments have been made in order to determine the so-called "reaction time" in sensation—i. e., the time between the moment of excitation of the senses and the moment at which the person indicates by a signal that he has become conscious of the sensation. M. Beaunis, of Nancy, has recently sought to measure the reaction time for smell. He gives (*Comptes Rendus*) a table of the numbers obtained with ten substances; they range from thirty-seven hundredths of a second for ammonia, and forty-six for acetic acid, to sixty-three for mint, and sixty-seven for carbolic acid. In the case of musk, he was unable (notwithstanding repeated attempts) to fix precisely the moment of the smell sensation. The numbers given show that the reaction time for smelling is longer than that for touch, sight and hearing. (In the author's own case, it is shorter than for touch.) Dr. Baccola, of Turin, has recently made experiments on smell, with different apparatus, and gets results which agree in the main with those of M. Beaunis.

SOUNDS PRODUCED BY FLOW OF LIQUIDS.—Researches relating to sounds produced by a stream flowing through a circular hole at the lower end of a long tube containing liquid have shown that the pitch does not change gradually, but that a definite number of distinct notes are heard successively as the liquid column shortens by the outflow. The pitch depends on the length of the liquid column and on the velocity of efflux. The number of vibrations is proportional to the velocity of efflux, and the sound is pure only when the sound of the vein is one of the proper sounds of the liquid column. A column of constant length gives notes in a harmonic series. When the sound is reinforced by the column of air above, it becomes quite loud. If the walls of the tube are prevented from vibrating, the sound ceases. The relative velocity of sound in different liquids may be determined by finding the lengths of the columns of liquid which give the same note, and the results thus obtained will be found to agree very well with determinations by other methods.

MORE ELECTRICAL EXPERIMENTS ON VEGETATION.—M. Macagno has experimented near Palermo upon the influence of atmospheric electricity on the growth of grape vines. Sixteen feet were submitted to the action of an electric current, by means of a copper wire inserted by a platinum point in the extremity of a fruit-bearing branch, while another wire connected the branch at its origin with the soil. The experiment lasted from April to September. The wood of the branches which were experimented upon, contained less potash and other mineral matters than the rest of the vine, but the leaves had an excess of potash under the form of bitartrate; the grapes collected from the electrified branches furnished more must, contained more glucose and were less acid.

A NEW EXPLOSIVE.—The Nihilists are reported to be considerably interested in a new explosive that is making quite a stir in Europe. It is the invention of Eugene Turpin, and glories in the name of "panclastite" or "brise-tout." It is said to be composed of two liquids, each non-explosive when alone, but when mixed together, just as wine and water are mixed, a fulminating compound is produced which can be exploded either by ignition or percussion. Experiments made at Cherbourg by the iron plate and the lead cylinder tests showed it to be much more powerful than dynamite, while by trial it was shown to be much less sensitive to a blow.

AN ANCIENT PERUVIAN BRONZE CHISEL.—At the meeting of the French Academy of Science on February 6th, M. Boussingault submitted to the members a bronze chisel harder than copper and not so hard as iron, composed of 95 copper, 4.5 tin, and traces of lead and silver. It is a specimen of the metallurgy of the Incas before their conquest by Spain, and has served to work the stone of Peru. It was found on the high-road between Quito and Cuzco. As to the supposed hardening that was given to bronze, M. Boussingault declared that he knew nothing of it, and had never been able to produce it.

SIERRA CITY.—*Mt. Messenger*, April 19: Considerable fine gold is still found in the top gravel of the One Thousand and One and Blue Gravel claims and the work of development energetically progresses.

Interest in quartz is beginning to revive in this section. The surprisingly large returns from the Marguerita, especially the latest clean up of \$25,000 for only a run of 28 days, conclusively proves to an unprejudiced mind, that the mineral resources of Sierra have been but partially developed. The Colombo ledge now bonded to Boston capitalists, must undoubtedly be as valuable property, if the rich quartz specimens, from the croppings, shown me, are a fair criterion. If but a very small proportion of the millions so lavishly expended on the Comstock, had been judiciously invested to unlock the golden vaults of these mountains of untold wealth of the Sierra Nevada, our deep, river canyons would be lined with quartz mills and the most prosperous mining camps in the world.

BRANDY CITY.—Sierra Tribune, April 19: The mining companies of this camp are taking advantage of the water season and sending down the debris to enrich the adobe soil of the foot-hills, which otherwise would be of little value for agricultural purposes, notwithstanding much has been said in regard to destroying that valuable branch of our industry. The Brandy City Co. has sufficient water for all purposes at present, although the ground is not of the richest kind. The company keeps washing away and has a force of about 40 men employed. This company wishes to let contract for running a bed-rock tunnel to that portion of their ground called the Windyvale claims, which is considered rich ground, and if once opened up would greatly enhance the value of their property. The Amott is likewise being worked this season, though the company is under the necessity of purchasing water. The claims will in all probability be worked out in about two years, provided they have water to work them. The Grizzly Hill mine owned by the Sharpe Bros., and on which they have bestowed their labor for over 20 years, is now in a favorable condition for working, although water is scarce within this year; yet the gravel they are piping away being on the bed-rock and void of clay pipe, they may clean up pretty well this season; for the time they may be employed washing. Their force is small, but only six men.

Trinity.
MINING OUTLOOK.—Trinity Journal, April 21: In view of the many nice showings which have visited this section with the past month, our people are greatly inclined to forgive the clerk of the weather for his apparent neglect during the winter. One month ago the mining outlook at this place was worse than had ever before been known, almost the last hope had departed and even the most sanguine felt certain that only a total failure could result from the unprecedented dry winter through which we had passed. Comparatively speaking, no work had been done in the hydraulic mines up to the first of April, and until the storms began a week before, it seemed more than probable that very little would be done after that date. However the storms have come liberally and in the best of order ever since they began on the 25th ultimo, and since the opening of the present month mines have been constantly employed in active operations. It does not now seem like predicting too much to say that the chances are good for three months sluicing; expenses for all hands are assured and to most of the owners of hydraulic mines the chances of a reasonable surplus on the season's work are more than good. The days are now long and freezing weather is past, so that nothing interferes with the free flow of water and the prosecution of work in the mines to the best advantage.

Tuolumne.
LAMPHEAR.—Union Democrat, April 21: Work under the new ownership of the Lamphear mine, has developed a vein 7 ft thick which shows gold generously. More than 50 tons of high grade ore was taken out in working up to trace the vein which does not crop out, or come to the surface. It is believed to be equally as rich as the Confidence mine proved some years ago.

NEVADA.
Washoe District.
UNION CON.—Enterprise, April 21: The joint Mexican east crosscut on the 2500 level shows but little change.

MEXICAN.—The joint Union Con. east crosscut on the 2500 level is still finding stringers of quartz of good appearance, but of low grade.

HALE & NORCROSS.—The drift on the 2600 level was extended south 65 ft, and developed some excellent ore, the average assays being over \$70. A drift has now been started north, and the ore streaks are looking well in that direction. The indications are that the ore is making in that direction.

OPHIR.—The joint Mexican east crosscut from the 300 station has passed through the belt of black porphyry which forms a kind of horse in the vein, and has now entered the usual channel of vein material.

POTOSI.—Some pretty fair assays have been obtained in drilling, but a good deal of water has been tapped and it has been necessary to plug up the holes. In crosscutting the indications are that good ore will be found at some point, as the ground is found to be fertile.

CALIFORNIA.—Sinking has been resumed in the C. & C. winze, which will be put down to the 2500 and connected with the main shaft drift.

CON. VIRGINIA.—The southeast drift on the 2500 level is exceedingly hot.

YELLOW JACKET.—The yield of ore from the 2d, 3d, 4th and 5th levels amounts to about 150 tons per day. The ground continues to look well.

CHOLLAR.—West crosscut No 2 has passed through some very favorable ground, and has cut several stringers of quartz of considerable width.

Bullion District.
ORE.—Austin Democrat, April 19: Mr. Robinson, who has been superintendent of the Bullion mine, 20 miles south of Beowawe, makes a flattering statement of the outlook of the district. He says there is ore enough to run a 10-stamp mill for a year. The old mill they have now is all worn out, and the roaster is old style and useless. A new ro-stamp mill and truckner furnace will be put up soon, and money made. The mine is owned by Dr. Frisbie, of Vallejo, L. Radovich, of San Francisco, and W. H. Ducommun and Lorey, who reside on the ground. There are many good prospects in Nevada, and every one will help make better times. The same company owns the Lady of the Lake and the Ivanhoe. Both have good ore, worth from \$100 up. A mile west of the mill is the Silverside, owned by Jas.

Campbell, with ore going from \$75 to \$900 a ton. There are lead ores nine miles further up the hill, owned by Twist brothers and Hoskins brothers. They ship ore to Salt Lake.

Columbus District.
NORTHERN BELLE.—Candelaria Free Press, April 20: The drift below the fifth shaft level has been advanced ten feet during the week, without developing any change in the formation. It is now in a total distance of 80 feet. A crosscut will be started east from the end of this drift to prospect the foot wall of the ledge. All the work in and about the mine is progressing in a satisfactory manner, the daily output of ore being about 55 tons. Both mills are running steadily, and doing good work. Five stamps of mill No. 2 have been engaged part of the week crushing a quantity of ore from the Great Western mine in Garfield district. The shipments of bullion have been \$22,642.51 for the week ending April 19th, and aggregate \$99,882.13 on April account to the same date.

MOUNT DIAMOND.—A little 500 ore is being extracted from the east drift on the second level, and the slope from the raise north of the shaft, on the second level, is yielding considerable \$75 ore. The west slope from the west drift from the Callison winze, shows two feet of ore assaying \$65 per ton, the one to the east has encountered 12 inches of \$90 ore. A small amount of \$100 ore is being taken from a point near the shaft on the first level. A shipment of bullion amounting to \$6,286.48 was made on the 12th inst., and another of \$8,759.22 on the 17th.

Comet District.
THREE PROSPECTS.—Pioche Record, April 19: Comet district mines are developing nicely. When a district can exhibit three good prospects, showing good quantities of fine pay ore, there are certainly good hopes for it, no matter what the formation of the district may be.

Florence District.
RATTLENAKE CANON.—Belmont Courier, April 14: From Charles B. Streicher we learn that the work of development is pushed constantly in the Sedan mine at Rattlesnake canyon, this county. The shaft has attained a depth of 130 ft, at the bottom of which the ledge is 4½ ft wide and still widening, as they go down. Assays made of the ore extracted from this ledge give as high as \$41 in gold and \$100 in silver. The ore will mill, on an average, between \$50 and \$60 to the ton. This is thought to be one of the very best properties in Florence district. Our townsman, Henry Bohle, is one of the owners.

Galena District.
A RICH STRIKE IN GALENA.—Eureka Sentinel, April 20: A rich strike was made in the McEwen mine, Galena, last Saturday, by the miners working in the main tunnel. The face of the tunnel is nearly all ore, and about 3 ft of it very rich. Persons who have seen the bonanza say that it is the richest prospect they have ever seen. The tunnel is now in nearly 1,000 ft; well timbered where necessary; with a good track and cars; but little water to retard operations, and the ground is easily prospected. About 135 ft of ledge carrying rich galena ore is exposed in the tunnel, which, at the present face, is about 200 ft in depth from the surface, giving a fine back for a slope. The full extent of the new find cannot be estimated at present, but it should certainly cause a stir in the camp and be the means of inducing those interested in mines to thoroughly prospect their claims. The McEwen mine is owned by Messrs. Blossom and Foster. These gentlemen have expended considerable capital in opening up their mine, and now will be amply repaid for their expenditures.

Jackrabbit District.
PROMISING.—Pioche Record, April 19: Some very nice looking samples of ore were brought to town from the King Fisher claim, Jackrabbit district, owned by Russell Fuller, Bailey Wilcox and J. C. Lynch. This claim is said to be the most promising in the district.

Lewis District.
THE BETTY O'NEAL ATTACHED.—Silver State, April 20: The Betty O'Neal mine, at Lewis, has been attached by creditors. Two of our lawyers, Judge Bonfield and J. H. MacMillan, have been up there attending to the interests of their clients, who are creditors of the company. The Anglo-Californian bank, of San Francisco, and Frank Watts and John Dias, of Lewis, are the principal creditors. The total amount for which the property has been attached is about \$8,000. This is bad for northern Lander.

Mount Cory District.
REDUCTION WORKS.—Walker Lake Bulletin, April 20: The Mount Cory Co. has decided upon the erection of reduction works, and is only awaiting the result of experiments to determine which will be the cheapest method. It is, however, generally understood that a mill will be built somewhere up the canyon for working such ore as can be worked by mill process, and that, in a few months, one of the several styles of furnaces will be built near Hawthorne, for working the refractory ore of the Mount Cory mine and base ores from other districts in the neighborhood.

Tuscarora District.
BELLE ISLE.—Times-Review, April 19: During past week drift No. 1 has been advanced 10 ft and drift No. 3, 15 ft, with no change to note.

NORTH BELLE ISLE.—During the past week the south drift has been advanced 18 ft. East crosscut advanced 12 ft and north drift 15 ft.

INDEPENDENCE.—During the past week the south drift, 400 level, has been advanced 17 ft, making a total distance of 534 ft.

ARGENTA.—Getting ready to slope above the 700 level next week.

GRAND PRIZE.—Water is gradually decreasing in it. West drift on the hanging wall on the 500 level is in 30 ft; vein is small; ore is good. Have commenced sloping ore above the 500 level.

NAVAJO.—The drift on the 450 level has been advanced 14 ft during the past week, and the east lateral drift, 350 level, was advanced 15 ft, with no change to note.

ELKO CON.—The ledge continues to look very encouraging and steadily improves as the drift is advanced. During the last few feet a stratum of blue kidney rock has been encountered, and looks very promising.

Tybo District.
PROGRESSING.—Belmont Courier, April 14: Work progresses satisfactorily in the 2½ mine at Tybo. We are reliably informed that large bodies of ore are exposed in this mine, enough, in fact, to run the company's 20-stamp mill for two years. It has never been disputed that rich mines exist in Tybo district, and, as soon as a railroad runs through that section, things will boom there. J. A. Donnel, of Tybo, informs us that the mine owned by himself and J. D. Page, an extension of the 2½, is looking uptop. These enterprising gentlemen have expended a considerable amount of money in developing this property, and there is no doubt that, in the near future, they will be richly rewarded for their pluck and energy.

ARIZONA.
BLACK HILLS MINING DISTRICT.—Prescott Courier, April 19: E. F. Thomas will start for this district to-day. C. B. Foster will accompany him. With them will go men who will at once commence opening roads, preparing sites for furnaces, etc. Mr. Foster will lay off the routes for roads. Mr. Thomas will act as general superintendent of the United Verde Copper M. Co., which company will shortly have 90 men at work. Wm. M. Butum, one of our oldest merchants, will very soon have a store filled with goods in the district.

YAVAPI MINES.—Prescott Courier, April 20: Prof. Geo. A. Treadwell, who is engineering the sale of C. C. Bean's magnificent copper properties, arrived from Mexico and southern Arizona a couple of days ago, and will remain in Prescott until Mr. Williams, of the Copper Queen mine, and a New York gentleman arrive here, when all will visit Mr. Bean's mines, which are, we learn, looking much better than when Mr. Treadwell last visited them, which change is, of course, due to the fact that, like most Yavapai county mines, the farther from the surface the richer the mine. The strike of rich gold rock in the Belle mine is what pleases members of the Howell company and all friends of this section. Gov. Tittle and his people have so far been very successful in securing means to develop Black Hills district. C. C. Bean proposes to do a great deal of mining in this vicinity as soon as that English company takes hold of his copper properties. One little job he proposes having done, is that of tunneling through and through Quartz mountain.

FOR WATER.—Pinal Drill, April 21: The work of sinking for water at the Queen Creek smelter is going on. The well is now 60 ft deep in solid clay almost impermeable to water. The sinking will continue until water is reached. As soon as that is obtained we expect that everything else will be in readiness for work.

MINERAL HILL DISTRICT.—Pinal Drill, April 21: We are informed that the Wide Awake M. Co. intend to renew the work on the Gem mine. It is also stated that work will be started on the Alice, in Mineral Hill district. Several other mines that have taken a rest are about to recommence their rustle, so that we expect lively times in Pioneer district this coming season.

RODGERS DISTRICT.—Pinal Drill, April 21: Messrs. Broerman & Sessler, of the World Benter, paid us a visit. They are working on their mine, extracting high grade ore, to be shipped and sold to the best advantage. They find their ore very profitable, and will probably make arrangements with some of the parties who are now contemplating the erection of smelting works in Rodgers district. W. T. Hutchinson has engaged Santos Corona, the experienced Mexican smelter, to erect one or more furnaces in Rodgers' district. This enterprise, if successful, will materially aid the mines in that vicinity, inasmuch as the transportation of ore for several miles must be by packing and a system of concentration of ore that will lower the freight. Rodgers' district is very favorable for smelting furnaces, there being timber in abundance for charcoal.

IDAHO.

ATLANTA MINES.—Idaho Statesman, April 20: The rich mining district of which Atlanta is the center is now on the eve of a grand boom, both in the extent of mining operations and results. The Monarch Company have their fine hoisting works in successful operation, and are pushing their main shaft with a strong force. Their hoisting machinery, both for capacity and completeness, is fully equal to any now in operation in Idaho or elsewhere. The Tahoma Co., whose mine is now well opened and ready to furnish ore to any extent, will have their crushing and reduction works in full blast as soon as the roads will permit the machinery to be brought in and put up. Other fine properties about Atlanta are in good working condition, and everything promises the most successful season the camp has ever experienced. The only drawback to the rapid development of the camp and to a rich yield of bullion has been and yet is, the isolated and almost inaccessible position of the camp, surrounded as it is on all sides but one by high and rugged mountains.

THE EAST FORK.—Wood River Times, April 18: Richard Lord, of Lord & Domski, has just returned from the East Fork of Wood River, and shows some remarkably rich ore from a ledge just discovered there by himself, near the Ben, Hauler group. One streak in the vein gives ore assaying \$1,400 per ton. He has come to town to settle his claim, and will take measures for its development without delay. He states that a number of the owners of claims on East Fork are arriving there and starting work on their properties, and a number of others are looked for daily. Superintendent Rogers, with 12 miners had arrived there and resumed work upon the Paymaster group, which is owned by the Philadelphia Co. New buildings will be erected, and work pushed ahead there, as well as at all of the camps.

MONTANA.

THE GAGNON.—Butte Miner, April 18: Among the few mines, in this or any other district, which have been operated at a profit, almost from the grass roots down, is the Gagnon, and the remark has not infrequently been made regarding this mine, that when the ore bodies on the surface were worked out there would be no mine left, but Col. J. C. Thornton, the efficient superintendent, thought different, and his confidence in the true fissure veins which had been developed under his own supervision in the mine was so great that he became the principal if not the sole owner of the property, and immediately thereafter began to sink for lower levels. In the west drift from the 400-ft station a fine vein of

high-grade ore was struck, which has proved something of a bonanza for the Colonel. Recently a 500-ft station, which is really 515 ft below the surface, has been opened and south and west drifts been run. The latter has tapped the vein which was developed in the 400, and ore is being extracted which runs \$300 to \$400 per ton. A winze has been started on the vein from the 400 to the 500, and developments from day to day confirm the existence of one of the greatest ore bodies ever uncovered in the district, which improves in size and grade with depth. This mine will be thoroughly developed below the 500, and is likely to be the first in the camp to demonstrate by deep mining the fact that our true fissure veins may be relied upon at a lower depth than has yet been explored.

STARTING UP THE BELL.—Butte Miner, April 20: The Bell smelter will be steamed up to-day and the machinery tested. If everything is found to work well, the smelter will be started up to-morrow morning on the ore already on the dump. The ore on hand is sufficient for 60 days run, by which time it is expected connection will be made between the new shaft and the old workings at the mine, which will furnish a regular ore supply for the future. When the smelter starts up to-day the fact will be announced by the blowing of the whistle at the Bell smelter, and other works will join in the chorus. The event is a notable one, and the shrill shrieking of a hundred steam whistles this afternoon will be a melodious sound to the ears of the entire community.

PHILLIPSBURG. James Burk, of the Salmon mine, at Phillipsburg, is spending a few days in the city. He reports the mines at the pioneer camp looking well, everybody is anticipating a good season, and claim owners are doing a good deal of representation work. People who own claims on Granite Mountain have a good thing and propose to hold it. The Granite Mountain and Hope mines are working full forces of men and hoisting plenty of ore. The Hope mill has been making a steady run, but has shut down for a few days to clean up and make necessary repairs.

NEW MEXICO.

SANTA RITA.—New Southwest, April 20: The San Jose Smelting Co. has purchased the coke held on hand by the Santa Rita people; a fair evidence that the Santa Rita is not to be started up an early day.

THE ore belts only have so far been developed in the Santa Rita property; others doubtless exist, and further exploration work will unquestionably disclose their location.

LOW GRADE ORE.—Between Bullard's peak and the Gila the country is covered with immense leads of low grade galena and carbonate ore. One mine recently located has a 35-ft vein of carbonate ore; many other leads averaging from 15 to 15 ft in width. The claims run very high in lead but carry little silver.

THE Hermosa, on Monument creek, is being worked by its owners, Messrs. Holmes, Holt and Deimer. They are now down 70 or 80 ft in a shaft, and have a good-sized engine of mineral which runs, on an average, \$160 in silver. The ore is a bonanza, very much like that of the Silver Monument, and the mineral streak which, on the surface, was only a few inches wide, has been constantly widening all the way down.

UTAH.

DEEP CREEK.—Salt Lake Tribune, April 20: The Deep Creek country gives promise of becoming a good mining district. During the past but little has been done there except to stake out a few claims and then neglect them. The distance from transportation, the difficulty of getting in supplies, the sparsely settled condition of the country and lack of capital have prevented progress there. Some months ago N. C. Springer went to that district and secured some prospects, which he deems so good that he came home and made preparations to go there and spend the summer in working them. He brought eight large teams from his ranch in Summit county to this city, and will load them to-day with six or eight tons of machinery, and with three tons of supplies, and full outfit for Deep Creek. The machinery will at once be put in operation, and the teams will be used for taking in supplies and hauling out ore. It is nearly one hundred miles from the mines to the nearest railway station on the Central Pacific, to which point he proposes to take his ore, thence to be shipped to this city.

The Mining and Scientific Press.

The miners of this coast have now known the MINING AND SCIENTIFIC PRESS so many years that it is scarcely worth while to call their attention to its important features, which are valuable to them in their calling. Yet there are many new comers who should take the paper who may not be familiar with it, and we hope our old readers will bring it to their attention.

We give every week a condensed summary of the current mining news, a condensed account of all that is new in science or mechanics, correspondence on suitable topics from all parts of the coast, illustrations of all the new improved machinery, especially that applicable to mining and metallurgy, timely editorials on topics suitable to a technical journal, metal markets, etc.

The Press is eminently practical, and we publish the results of experience as fast as it is gathered. In the matter of describing new mining appliances, inventions, metallurgical processes, etc., the Press stands alone. No man interested in mining matters can afford to be without it. When new districts are discovered we present maps and descriptions and collate from every source all that will be useful to our readers. Any reader looking over this number of the Press will see how useful such a journal will be to him in his business.

Latest Instructions to Settlers upon the Public Domain.

(CONTINUED FROM PAGE 282.)

than five years; and shall, moreover, thereafter be incapable of giving testimony in any court of the United States until such time as the judgment against him is reversed.

Sec. 5393. Every person who procures another to commit any perjury is guilty of subornation of perjury, and punishable as in the preceding section prescribed.

Sec. 5440. If two or more persons conspire either to commit an offense against the United States, or to defraud the United States in any manner or for any purpose, and one or more of such parties do any act to effect the object of the conspiracy, all the parties to such conspiracy shall be liable to a penalty of not less than \$1,000, and not more than \$10,000, and to imprisonment not more than two years.

Sec. 5479. If any person shall falsely make, alter, forge, or counterfeit, or cause or procure to be falsely made, altered, forged, or counterfeited, or willingly aid or assist in the false making, altering, forging, or counterfeiting, any bond, bid, proposal, guarantee, security, official bond, public record, affidavit, or other writing, for the purpose of defrauding the United States,

San Francisco.

As San Francisco is the great center and distributing point of the Pacific coast, we deem it appropriate to an issue devoted to immigration matters to present a view of the city whence nearly all new comers come before selecting their future locations. The view is taken from an imaginary point northeast of the city.

San Francisco is the youngest of America's great cities. The exact date of settlement or founding may be claimed for the time when the site of the Mission was first selected by Portala and Crespi, in 1769, or when the Mission and Presidio were established by the good friars, Palou and Cambon, in 1776; or when Richardson, in 1835, located here and established a trading post, calling the place Yerba Buena; or when Visoet, in 1839, surveyed the ground into streets and squares; or when, in 1847, the Americans in possession resurveyed and enlarged the area, and gave it the name of San Francisco. A mediæval obscurity surrounds its early settlement and progress. The religious spirit of the middle ages, even to a late date in the eighteenth century, still governing the Spanish people, prompted its devotees to penetrate the wild regions of the new world, to spread the doctrines of the church and gather

cisco may be regarded as the objective point of all railroads of the Pacific coast, but more particularly so of all in California. The city is fixed as the natural center of commerce of the whole west coast of North America. The great rivers, valleys and mountain passes lead unerringly to this point, and thus converge the channels of inland trade from all the surrounding States and Territories. The broad bay affords one of the best harbors of the world, and the Golden Gate opens to the Pacific and all the maritime nations of the earth. The currents of the air and the ocean so aid the other advantages, that the location is perfected as a center of commerce. The conditions of location and climate insure to San Francisco a higher degree of health and exemption from known epidemics than is vouchsafed to most other large cities of the world. Situated upon a narrow, rocky and hilly peninsula, with the broad Pacific on the west, and the capacious bay and straits of Golden Gate on the east and north, with their swiftly flowing tides, keep its surroundings washed and pure, while the prevailing winds, through the warm, dry summer pour freely upon it from their long sweep over the ocean where they have gathered the elements of health, uncontaminated by the malaria of dying vegetation or the miasmatic poisons of inhabited lands. Nature having

ores thousands of miles by wagon and rail to eastern works after we have failed in the profitable working at home. The Colorado idea is one which should commend itself to the mine owners and capitalists of the county as the only feasible solution of the question of economical treatment of ores, and should be adopted to the entire exclusion of the monumental folly that would fill our gulches with worthless cast iron rattletraps in no way fitted to perform the duties required of them. We believe the Howell works, on Lynx creek, a right step in the proper direction, but as the capacity of even Mr. Howell's extensive plant is not sufficient for the requirements of this section, we hope to see similar other enterprises started in the heart of the rich mining country south of Prescott.—*Cor. Prescott Courier.*

Walnut Grove Mining District.

Mr. Moroney tells us that John Tiedman and a man named Johnson recently found a ledge which prospects well in gold. It is situated about two miles east of Callen's camp at the Piaceritas. The finders are at work sinking a shaft.

Yarnell and Sistro are taking rich gold rock from a mine near the Vesnivins.

Sanchez, who has been getting \$1,000 a month

BIRD'S-EYE VIEW OF SAN FRANCISCO.

or shall utter or publish as true, or cause to be uttered or published as true, any such false, forged, altered, or counterfeited bond, bid, proposal, guarantee, security, official bond, public record, affidavit, or other writing, for the purpose of defrauding the United States, knowing the same to be false, forged, altered, or counterfeited, or shall transmit to, or present at, or cause or procure to be transmitted to, or presented at, the office of any officer of the United States, any such false, forged, altered, or counterfeited bond, bid, proposal, guarantee, security, official bond, public record, affidavit, or other writing, knowing the same to be false, forged, altered, or counterfeited for the purpose of defrauding the United States, shall be punishable by a fine of not more than \$1,000, or by imprisonment at hard labor for not more than ten years, or by both such punishments.

LA ROSE DAVELTY has given the Lamphere mine at Confidence to Johnnie Davis & Co., in consideration that the company will give him the contract for furnishing poles, etc., for the mine when operations shall have commenced. La Rose, who is a grocer in the locality, argued that the mine would probably never be opened by himself, and if there was anything in it, it had better be taken out and circulated.—*Tholomine Independent.*

It is reported that ex-Governor Blasdel has sold the Humboldt group of mines at Aurora for \$150,000.

the heathen under its care, rather than to enlarge the sphere of human liberties, or pursue wealth by extending commerce or developing the resources of the country.

Under such auspices was the site of the city selected and occupied, thus giving in the brief period of a century an ancient character to its history, advancing with a bound as it sprang from Spanish to American rule—from the semi-civilized past to the enlightenment and activity of modern times. The peculiar features of the city were not obliterated by the change. Ancient and simple as it was in its origin, it has become the most busy and cosmopolitan of the age. Every State of the Union has its representative, and from every quarter of the globe have come its citizens: the language of every commercial people is spoken; every color which the human visage bears is seen, and every religion has its worshippers. These characteristics of cosmopolitanism distinguish the modern city from its sisters as did its mediæval features of early years from the settlements of the Atlantic coast.

In April, 1856, the limits of the present city's territory were fixed by law. The southern boundary is the U. S. land survey of the line separating townships two and three south of Mt. Diablo base and meridian. The Farallone, Angel, Alcatraz and Goat islands are included in San Francisco city and county. The boundaries are the Golden Gate on the north, the Bay of San Francisco on the east, San Mateo county on the south, and the Pacific ocean on the west. The land area is 42 square miles, or 26,880 acres. San Fran-

thus provided, it has been easy to preserve a high order of health; and indeed it were criminal in the extreme, and a blot upon our boasted civilization, should our city show a large percentage of mortality or excessive sickness.

Ore Veins and Reduction Works.

The experience of mining communities elsewhere goes to further the opinion that mining and milling operations are best conducted where they are not combined under a single management. The practice of locating small mills on single claims is rapidly giving way to that of having larger and more complete mills erected at central points, to which the product of many mines are made to contribute. This is eminently the Colorado idea and is the natural outgrowth of rebellious ores and rich but small veins. The cost of transporting ores to such mills and reduction works is more than offset, in most cases, by the larger percentage of the precious metals saved under superior management, costlier appliances and the superior facilities of these large works. It is one of the very palpable causes of failure in mining enterprises in Yavapai county in the past, that neither the money nor experience of certain mine owners who essayed the treatment of their ores at the mines were adequate to the attainment of even fair results. The character of our ores is such that only expensive appliances can successfully and economically treat them, and we have the example presented to us of shipments of ou-

in his arastras, has sold one half interest in his properties.

Chispas, weighing from one dollar to sixty dollars, have, of late, been found in the gravel and on the slate bedrock. When the Mulvane ladies, of Kansas, were at the diggings with their husbands, they washed out considerable gold, a fact which pleased them very much.

A new ten-stamp mill, built in Denver, Colorado, is on the ground and will be up and running inside of ninety days. Each stamp weighs 600 pounds. The engine is a twenty-five horse power, Westinghouse; the mortar is different from the California mortars and, it is thought, far better. Mr. Bolthoff, firm of Bolthoff & Hendrie, of Denver, which firm makes these mills, will come down and superintend its erection. With it came timbers, etc., all ready for the machinery.

These mines—quartz and placer—of the Callen company, are between Peoples Valley and Walnut Grove, where, besides mineral, wood, water and grass are abundant.

It is the opinion of old and new settlers who know the section and its resources that the company can, if they work things rightly, amass large fortunes out of the mines now owned by them.—*Prescott Courier.*

A PUMP in the Grand Central mine at Tombstone is successfully at work, and it will soon be demonstrated whether ore deposits exist below the water line in that region.

Walker Mining District, Arizona.

The above named mining district is in Yavapai county, between ten and twelve miles from Prescott, in a southeasterly direction. To get there by wagon, a person goes north, a little over a mile, via Whipple Barracks, thence east to Lynx creek, the general course of which stream is followed to the Howell Quartz Reduction works, around which now congregate a great many busy people.

Another way, and a shorter one to get there, is by the trail which crosses Banning and Groom creeks. This is the shortest way. Juniper, oak and pine trees are plentiful on both routes, as are water and grass. The altitude of the region, from 5,500 to 7,000 feet above the level of the sea, the ever circulating breezes, mostly from the south, make it a very healthy region. Water is always cool and pure. From the high mountain peaks around the smelter, a person can gaze upon what may be termed a sea of pine, beyond which are charming valleys, where people who raise supplies for the miners dwell in peace and have plenty of the world's good things. In 1862, when the late Capt. Joe Walker led the first party of prospectors and miners into this part of the territory, they selected Walker district as the best place for their operations. The woods were well stocked with bear, deer, turkey and other game; the gravel of the creeks was well charged with gold, in small and large particles, while quartz ledges, carrying gold, silver, lead and other metals were to be seen on every hand.

Taking the whip saws which the party had brought with them, lumber for rockers and shies were easily made out of the grand pine trees of the district, claims were staked off, log cabins erected and the work of gold getting commenced. The diggings paid well for the most primitive kind of mining; gold dust was in every man's pocket and cabin, and no fault was found with the country. Miners flocked in from California, Colorado and other places. While there was but little of the law that is known in so-called civilized regions, our pioneers attended to their business, order reigned and nothing occurred to make anybody afraid until neighboring Indians commenced to keep aloof from the miners, to look ugly and threatening. The adventurers had treated the aborigines well; they shared with them their provisions, clothing and tobacco; but savage nature wanted more; they commenced to steal horses, mules and donkeys from the miners and to lay in ambush and kill them. This was the way trouble started in the first settlement made by Americans in central Arizona. This was when it became exceedingly disagreeable for white men to reside here. A great many fell by the wayside; those who survived held the country "by the skin of their teeth," as the saying goes.

The richest of the placer mines were soon worked out, and the great cost of the necessities of life, together with the Indians, deterred many men from attacking poor diggings with pick and shovel. So population kept decreasing until what was once the largest mining camp in Arizona, became a very insignificant one.

Attempts were at various times made to work the quartz by mill and arrastra process. Some men were very successful, but as depth was attained sulphurets became thick and the miners were not, of course, fixed with machinery for the treatment of the "rebellious" particles.

The Howell Milling, Mining and Smelting Company have, at great expense, prepared themselves with machinery to treat all classes of ore; they have infused new life in Walker and adjacent mining districts and will, we believe, solve the grand problem which has so long bothered old Hassayamplers—"Can sulphurets be worked with profit?"

Having recently sent William S. Hodges, one of our young men, over to the Howell camp, we below give the result of his observations in his own language:

A visit to Lynx creek will convince anybody of the future prosperity of the district.

Howell Smelting Works.

In company with Mr. Geo. B. Schoonmaker, who is connected with the Howell Mining, Milling and Smelting company, we visited the works and through his courtesy, obtained the following information concerning them:

There was about \$50,000 worth of crushed ore on the dump, most of it paid for, representing fifteen mines. Among them are the Happy Jack, Dosoris, Kittie, Middleton and Silver Belt. The crusher, roaster and saw-mill are running daily; in the cooling room there are about sixty tons of roasted ore, ready for smelting. The smelter will commence its operations in about thirty days. The company also has about 25,000 bushels of charcoal burned and burning, besides several thousand cords of wood; the saw-mill has sawed 200,000 feet of lumber since it started. The company has a stamp mill and concentrator on the way.

Col. C. C. Lane, the company's secretary, is in the camp. Some of the directors are expected to arrive in a few days.

The company have built good wagon roads to their mines. Their teams make daily trips and bring in from ten to twelve tons of ore per day.

Three pack trains of about twenty mules and burros each, make two trips daily to the Kittie, Silver Belt, Dosoris and other mines in the district.—Prescott Courier.

USEFUL INFORMATION.

Crackled Glass.

The *Moniteur de la Ceramique* gives the following description of Bay's process for making the new kind of glass, which is smooth on one side and rough on the other. The roughened surface of the glass looks as if it was covered with cracks, and this appearance is obtained by spreading over the surface of the glass a thick layer of some flux, or easily fusible glass, that has been made fluid or pasty and mixed with coarser pieces. The glass is then put in a mill or an open furnace and strongly heated. As soon as this flux is melted and the glass itself becomes red hot, it is taken out of the furnace and rapidly cooled. This flux or fused glass then cracks off from the other glass which was attacked by it, leaving numerous depressions in the latter resembling scales and irregular crystalline forms, crossing and intersecting each other and producing very beautiful effects when the light falls upon it. This fusible layer is cooled as rapidly as possible, either by a current of cold air, or by carefully sprinkling with cold water.

If some portions of the glass are protected from the action of the flux, the surface remains smooth, there is a striking contrast to the crackled portion. This can be utilized in making arabesque, letters, and other designs on a white or colored ground.

A similar crackled glass is made in another way, by strewing a coarsely grained flux on a cylinder of glass while still red hot, and then putting it back in the heating furnace until the flux melts. It is then rapidly cooled, either by sprinkling water on it or waving it back and forth. The layer of melted flux then cracks off and exposes the surface of the glass which has been corroded by it. The cylinder is then cut and spread out in the usual manner.

BEST TIME TO CUT TIMBER.—A correspondent of an Eastern journal says: "For strength, beauty and durability I have found August, September and October the best, and February, March and April the worst months to cut wood. A red maple cut in September will keep in a round log perfectly white and sound until the next August; while one cut in March will begin to blacken and decay by the middle or last of June. This is not copied from any scientific work, but is what I have found to be a fact by many practical tests. Gray birch cut in September will keep in a good condition until the next September if left in the woods cut in four foot lengths; while if cut in March and left in the same way it will be nearly worthless by the first of August; at least such is the result on my land. White pine, like the red maple, keeps white much longer if cut in September than if cut in March, and is not injured by the worms as much. I have found that wood dried slowly in a low cool place is better than dried quickly in the hot sun, even though cut in summer. May this not, in a measure, account for wood being better cut in autumn, it having the long cold winter to dry in?"

CELLULOSE TO BE SUPERSEDED.—A new material has been invented, which, according to the *Tradesman*, it is thought will supersede celluloid. It possesses all the hardness and brilliancy of the latter, and has the advantage of being fire-proof. It is made in this way: A solution is prepared of 200 parts of casein in 50 parts of ammonia and 400 of water, or 150 parts of albumen in 400 parts of water. To the solution the following are added: Quick lime, 240 parts; acetate of alumina, 150 parts; alum, 50 parts; sulphate of lime, 1,200 parts; oil, 100 parts. The oil is to be mixed in the last. When dark objects are to be made, from 75 to 100 parts of tannin are substituted for the acetate of alumina. When the mixture has been well kneaded together and made into a smooth paste, it is passed through rollers to form plates of the desired shape. These are dried and pressed into metallic molds previously heated, or they may be reduced to a very fine powder, which is introduced into heated molds and submitted to a strong pressure. The objects are afterward dipped into the following bath: Water, 100 parts; white glue, 6 parts; phosphoric acid, 10 parts. Finally they are dried, polished, and varnished with shellac.

EFFERVESCENT LEMONADE SUGAR.—The manufacture of effervescent lemonade sugar is said to be as follows: Five parts of powdered sugar are treated with an ethereal oil, and mixed with one part of bicarbonate of soda. This mixture is filled into candy molds, and pressed by means of a stamp. Within the mold a cavity is produced in the mass by the pressure, and into this there is poured one part of citric acid, which is pressed down, and then a fresh layer of aromatic sugar is added and pressed, after which the candy is finished.

LONG DISTANCE TELEPHONING.—If the Western Union Telegraph Co., as is stated, has purchased the right to use Baxter's long distance telephone, it will not be long before conversation can be carried on between San Francisco and New York with probably two breaks only.

SPIRIT OF TURPENTINE is now made, says a contemporary, from sawdust and refuse of the saw-mill. It is extracted by a sweating process, and yields fourteen gallons of spirits, three to four gallons of resin, and a quantity of tar per cord.

A VALUABLE building stone has recently been discovered near Albany, Oregon, upon which the action of neither heat, cold, nor moisture has any bad effect. It is one of the most important events that has ever occurred in the Territory. The stone is called granite sandstone, very rich in silica, of a close, fine grain, highly crystallized, unlaminate, and of a fine brown color. It has been used in this locality for many years, for fireplaces, door and window sills, and for monumental work. It has lately been put to some very severe tests, with a view to using it for the building of the great union depot at Portland. It was brought to a white heat, and suddenly plunged into cold water, and came out as solid and firm as before it went into the furnace.

BRICKS OF CORK. At the Nuremberg exhibition was shown a novel use of bricks of cork. These bricks have only been used for building purposes on account of their lightness and insulating properties, but they are also employed as a covering for boilers, and are said to excel even asbestos in preventing the radiation of heat. They are stated to be very cheap, being prepared of small corks, refuse and insulating cement. At Nuremberg, the application of cork bricks was largely shown. The usual size of cork bricks is 10x4x2½ inches.

A RAIL for common use has been introduced into France. It is imbedded in concrete, and is flush at the edges with the roadway. From the sides it slopes down to the center, so as to enable the wheels of vehicles to retain their place upon it. The estimated cost is about two dollars a yard. Other countries are also considering this.

IMPORTANT POSTOFFICE DECISION. A recent decision of the Postoffice Department is to the effect that a letter, after being sent, can be recalled by the sender upon his making application to the postmaster, who has authority to recall the same by telegraph.

GOOD HEALTH.

Pneumonia, Lung Fever and Kindred Diseases.

Dr. C. E. Page communicates to *Cotton, Wool and Iron*, a Boston publication, an excellent and suggestive article under the above head, which is of special interest in this latitude, because of the increasing number of deaths which are occurring among us from pneumonia. The extracts which we give from the Doctor's paper contain some pertinent points which are well worthy of careful consideration:

Pneumonia is, or should be, classed among the fifth diseases, with croup, diphtheria, scarlet fever, measles, etc. Whatever may be thought of these disorders, it is certain that pneumonia is not contagious. No person ever has it who habitually breathes pure air twenty-four hours in the day, and who lives on even approximately pure food (excess of even the purest food tends to impurity because of indigestion.) "Plain livers" seldom, abstemious vegetarians, those at least who know as much about air as they do about food, and whose practice corresponds to their knowledge, never have this disease. Physicians of all schools agree that sedentary persons, living in very warm rooms, should eat little or no meat, since this class of food requires active exercise in open air to "work it off." The condiments, spices, hot sauces, etc., associated with animal food, are a constant tax on the stomach and intestines, irritating them, besides directly contaminating the blood with unnatural elements.

Alcoholic drinks predispose to this disease and to all kindred disorders, preventing the normal waste of tissue; hence the plumpness of persons at certain stages of alcoholism.

Coffee and tea, as physicians well know, are in certain respects identical with alcoholic drinks in their physiological effects. They "lessen the waste," and the waste is what keeps the body clean.

Old age is regarded—rightly enough, too, in one sense—as a predisposing cause of pneumonia; but this arises mainly from the fact that old people are more likely to realize the waning powers of the voluntary muscular, than the digestive, system, and are more certain to curtail their fresh air, than food, rations.

Indigestion.

However caused, is, next to foul air, the cause of the generation within the system of impurities, which may, by their accumulation, produce finally one of the sicknesses I have named. A single excessive, or especially unbalancing meal may, where the predisposition exists, excite a fatal attack of pneumonia; and to skip a meal altogether, or to treat the system to a veritable fast day, would, by resting the alimentary apparatus and permitting the excretions to have "everything their own way" for an even twenty-four hours, be a most effectual preventive remedy for every one, who has any suspicion as to his or her physical condition.

Grief, anxiety, anger, etc., anything that tends finally to depress the physical state, is adverse to the digestion of food and the due nutrition of the body, and hence is promotive of disease. On the other hand, wholesome food, "the gospel of not too much," fresh air, exercise, constant ventilation of living and sleeping rooms, the cultivation of a fair and friendly spirit—all this tends to make a sound, clean body that cannot harbor disquieting emotions such as are named above.

The night air superstition continues to "side in" with the doctors, druggists and undertakers, and ought to have been buried in the same grave with its companion humbug, "no water in fever." We can only have night air at night, and it is purer on the outside than inside the dwelling, even with the best of ventilation, but when we shut up a roomful and breathe it over and over again, it is like washing in and drinking from the same pail. If the room breathes only through the crevices of the doors and windows, its occupant breathes in the same manner. Think of taking one's soup through the key-hole.

Everything that tends to depress the vital forces operates as a predisposing cause to pneumonia, or some other of nature's kill or cure remedies; for what we term diseases, generally, are attempts, and in ninety-five in the one hundred cases of sickness, successful attempts of nature to cure the disease from which the organism has been suffering for a longer or shorter time. Build up the system, then, by every available means. Ascertain, as best you may, what constitutes good living in a physical sense, and by use it will become the best living in every sense, insuring a greater degree of all the pleasures of life, and counteracting, so far as possible, all adverse hereditary influences.

The doctor quotes from another writer, who, in speaking of the effects of cold, or outdoor exposure, as an exciting cause for pneumonia, says: The victim may have exposed himself to weather too severe in itself, or comparatively too severe, because of the comparative resistive power of his system through debility. Consequently, it is, in a great many cases, a malady that the thoughtful man may escape. He may go out on a March night to come home and have pneumonia, or stay at home and be without it.

The reason of the above is that the cause of the disease exists in the system, which a slight exposure may bring out sooner than it would otherwise appear if special care was taken to prevent it. Moreover, the disease is quite as likely to be precipitated by the coming into a warm, unventilated room, as from the cold encountered during the walk. Impure food and unhealthy condition of the digestive organs is more likely to cause, and more often does cause, pneumonia than exposure to cold out-door air, whether in night or day time.

A CURE FOR SCIATICA.—A correspondent, writing to *London Family Fair*, says: "A cure for neuralgia and sciatica, and, as I am told, an unfailing one, is too valuable not to be recorded. An English officer, who served with distinction in the war with Napoleon, was once laid up in a small village in France with a severe attack of sciatica. It so happened that a timman was being employed in the house where he lodged, and that this timman, having been himself a soldier, took an interest in the officer's ease, and gave him the cure, which, in this instance, succeeded immediately and forever, and which I am about to set down. It is at any rate so simple as to be worth a trial. Take a moderate sized potato, rather large than small, and boil it in one quart of water. Foment the part affected with the water in which the potato has been boiled, as hot as it can be borne, at night before going to bed; then crush the potato and put it on the affected part as a poultice. Wear this all night, and in the morning heat the water, which should have been preserved over again, and foment the part with it as hot as can be borne. This treatment must be persevered with for several days. It occasionally requires to be continued for as much as two or three weeks, but in the shorter or longer time it has never yet failed to be successful.

EFFECTS OF ELECTRICITY UPON THE NERVES AND HEART.—Among the curious exhibits at Munich Electrical Exhibition were a series of photographs representing the various changes and contortions produced in the human face by subjecting the different facial nerves of a patient to the action of electricity. These were the experimental photographs made by Professor Von Ziemssen. The expressions of joy, pain, surprise, doubt, disgust, etc., were easily realized, according to the nerve that was touched by the electrode. Other observations and experiments by Professor Von Ziemssen promise to be of great importance. They institute a comparison between the continuous and the induced current in the stimulation of the important accelerator and depressor nerves which control the heart. He has found that an induced current, so far from stimulating the nerves of the heart, as heretofore believed, is perfectly inoperative, whereas a continuous current from an ordinary battery is of the very greatest activity.

SIT ERECT.—One of the worst habits young people form is that of leaning forward too much while at work or study. It is much less tiresome and more healthy to sit or stand erect. The round-shouldered, hollow-chested and almost deformed persons one meets every day could have avoided all the bad results from which they now suffer had they always kept the body erect, the chest full, and shoulders thrown back. A simple rule is, that if the head is not thrown forward, but is held erect, the shoulders will drop back to their natural position, giving the lungs full play. The injury done by carelessness in this respect is by compressing the lungs, preventing their full and natural action, resulting in lung disease, usually consumption. Sit erect, boys and girls, and look the world in the face.

Ore Pulverizer—W. L. Tustin, San Francisco.

Passing Events.

In reading over the various exchanges pub-
lished in the mining camps of this coast, we have
been struck with the wide range the mining in-
terests now cover. In some places they are hard
at work on their claims and in others the
weather is just beginning to let them go to
work. In certain localities, prospecting has
been going on for a month or more, while in
others, there is still snow to retard progress in
this direction. Several strikes are noted in the
various camps.General Crook has this week commenced
his campaign against the Indians in Arizona.
The expedition is fully equipped and supplied
for ninety days. It is supposed the fight will
be in Mexico, but at all events it is probable
that Crook will stop further raiding on the part
of the Indians.We publish this week a double edition de-
voted to the interests of Arizona, which how-
ever, contains also a great deal of value to the
general reader.MICA MINE.—Our regular correspondent in
Arizona, Mr. Crowell, writes us that recently
J. M. Bunkell, W. J. Perry and P. C. Healey,
brought into Tombstone some fine specimens of
mica from a new location in the Matucopa
mountains, Arizona. They brought in large,
thick blocks right from the surface, with the
surface moss clinging to them. One sample
was 11x12 inches and of fine cleavage and tough,
only slightly smoked. Some specimens were
very clear and white. The location is only ten
miles from the railroad. Two of them took out
500 or 600 pounds in about two hours.

Arizona Copper Mines.

Nowhere throughout the Pacific coast region
are the cupriferous deposits more widely dis-
seminated or of better quality than in this Ter-
ritory. Remarking on this subject in a general
way, Hinton, in his "Handbook to Arizona,"
observes that the copper districts are scattered
over nearly the entire country, the principal
sites of active production, so far as this indus-
try has been prosecuted, being at Clifton, in
Apache county; at the Planet mine, Mojave
county; at the Copper Queen mine, Pima
county, and at the Old Dominion mine in Globe
district, Pinal county. Some five or six smelt-
ers have within the past year or two been
erected and gone into operation in various other
parts of the Territory, the above-named con-
sisting of works that have been running for
several years and already made a considerable
production. Copper ores were raised and
smelted in a rude way at the old Ajo mine and
at some other places in Yuma county by the
Mexicans many years ago. The first cupriferous
deposits worked in Arizona since the Ameri-
can occupation of the country are situated in
Mojave county, at a point about three fourths
of a mile south of Bill Williams' Fork and
twelve miles east of the town of Aubrey, on
the Colorado river; these deposits constituting
what is now known as
The Planet Mine.Copper ores of high grade were discovered
here as early as 1863. In 1864 a company hav-
ing been formed in San Francisco for working
these mines, operations were commenced the
following year, and have, with considerable in-
termissions, been prosecuted ever since. The
quantity of copper produced here amounts to be-
tween eight and ten thousand tons, made from
ore that has averaged perhaps thirty-five per
cent metal. The scarcity of wood and water
in the vicinity has proved a great detriment to
mining. Transportation of supplies for the
mines and of bullion to market has also been
costly, uncertain and inadequate. Of late but
little has been done at the Planet mine, but as
the line of the Atlantic and Pacific railroad
passes near it, work will probably be resumed
here at no distant day. Some developments
have also been made on the Apache Chief, a
promising copper vein in the same neighbor-
hood.The next of those modern exploitations for
copper in Arizona was undertaken on the series
of lodes owned by the Longfellow company,
better known as

The Clifton Mines,

Situated in the extreme southeastern part of
Pima county, near the New Mexican line. Al-
though laboring under immense disadvantages
until lately, since the railroad approached it,
this mine has made a very considerable and
highly profitable production during the past six
or eight years. The ore here, chiefly the red ox-
ide variety, occurs as in most other places in
Arizona, in strong veins lodged between
quartzite and limestone, or wholly in limestone,
and has averaged as it came from the mines,
twenty-five per cent metal. The ore bodies of
this grade are from ten to fifteen feet thick. The
cupriferous zone at this point can be traced for
several miles, though the richest section of it ap-
pears to be in the vicinity of Clifton. Although
some of the veins have been opened to a depth
of 500 or 600 feet, no deteriorations of the ores
have occurred here. Some copper glance, with
occasional bunches of pyrites have come in, but
not enough to effect the general character of the
ore. For some time, at first, only the rudest
kind of smelters were in use here. Latterly, how-
ever, more complete works have been con-
structed. The practice at these mines has been
to reduce the ore to black copper containing
ninety per cent metal by smelting with pinyon
charcoal, of which about 500 pounds are required
for each ton of ore.This charcoal is burnt at a distance of ninety
miles from the mine, and costs, delivered at the
furnaces, \$30 per ton. Until recently the prod-
uct of these mines was hauled with ox teams
to El Moro, in Colorado, 750 miles, at a cost of
\$80 per ton of 2,000 pounds. At El Moro it
was shipped by rail to Baltimore, a distance of
2,500 miles, at a further cost of \$20 per ton.
The cost of mining and reducing on the ground
to black metal has, until lately, averaged \$160
per ton, refining at Baltimore having involved
a further expense of \$40 per ton, bringing the
cost of one ton of pure metal up to \$300, which,with the price of copper as low as it is at present,
would have left but little margin for profit.
Besides a saving of about \$70 per ton in freight-
ing to the seaboard, other economies have recently
been effected in the business of copper produc-
tion at these mines.While the Planet first, and the Clifton mines
at a later day, were the most productive in
Arizona,

The Copper Queen

Stands now the big mine of the Territory, its
net annual product rivaling that of the great
silver mines in the Tombstone and the Pioneer
districts. This mine is situated in what are
known as the Mule mountains, being about
thirty miles from Fairbanks, on the Atchison,
Topeka & Santa Fe railroad, and about eight
miles from the line of New Mexico.The last annual report of the Copper Queen
Company issued one year since shows the fol-
lowing facts: At the time the company came
in possession of this property, not quite three
years ago, although but little work had been
done upon it, there were estimated to be in
sight over 34,000 tons of ore above the first level,
which had been prospected by a drift not over
ninety feet long, no crosscutting having as yet
been done. The work of further exploration
was at once begun and prosecuted with such
vigor and success that the ore reserves by April
1, 1881, held not less than 83,000 tons of ore,
18,108 tons having meantime been extracted
and smelted. The value of the copper turned
out during the year ending April, 1882,
amounted to \$1,020,859; operating expenses,
including freight, refining, etc., amounted to
\$532,733, leaving as net earnings for the year,
\$488,126, out of which \$300,000 were disbursed
to the shareholders in dividends—surplus profits,
\$188,126. During the past year the net
earnings of the company have amounted to
\$600,000—\$500,000 of which has been paid out
to the shareholders in quarterly dividends of
\$250,000 each. The company calculated that
they have ore enough in their reserves to
keep up the present rate of production for
years to come. The reduction works here
consist of two water-jacket furnaces, having
capacity to smelt about eighty-five tons of ore
per day, producing about 22,000 to 25,000
pounds of black copper. With their present
stock of ore the company might well largely in-
crease the reduction capacity, though it does
not appear that they intend to do so, being
satisfied with the present earnings of the mine.
The amount for 1882 was 4,033 tons, 956 pounds
of black copper, averaging ninety-six and one
half per cent.

The Old Dominion Company.

The old Dominion Copper Company owns mines
at Globe (the Globe and Globe ledge) the Key-
stone and Old Dominion mines, two and a half
miles from Globe, the Black Copper group six
miles from Globe, in Mineral Creek district.
The furnaces are at Globe and the ores of
the Old Dominion and Black Copper group
not being worked at present. The No. 1
furnace began work June 13th, 1882,
but has not been run steadily owing to
lack of fuel at times. Up to April 18th the
company has produced 2,824,200 pounds of cop-
per or 226 running days of one furnace, or an
average of 72,000 pounds per day. They are
running now two furnaces producing from ten
to twenty tons per day. The full capacity is 150
tons of ore per day, and from twenty-five to
thirty tons of copper.Among other copper mines in Arizona that
have already made a considerable production or
will soon be in a condition to do so, are the
United Verde, the Chase Creek, the Coronado
group, Castle Creek, the Copper King, Copper
Mountain, and several properties in Dos Ca-
bezos district; the prospect being that the out-
put of copper in the Territory will be greatly
increased for several years to come.

Silver Bell District, Arizona.

From Our Traveling Correspondent, B. W. C.

The Young America group consists of five
full and two fractional claims in Silver Bell
mining district, which is forty miles west of
Tucson. At present they have leased the Pima
Copper Co.'s smelter at Felton, four miles away
and will start up smelting on high grade copper
ores. They expect the whole fluxes and all, to
average fifteen per cent. Iron hematite ore with
five per cent copper, and ninety per cent iron.
There is lime rock on the claims. They are now
waiting for teams, to haul ore from the mines to
the smelters, and coke from the railroad to the
smelters. The depot of Kilitito, is seventeen
miles west of Tucson, the railroad point of sup-
plies. They expect to reduce daily thirty tons.The water jacket furnace is in charge of Mr.
Horbury, or "Uncle Jesse," a very successful
metallurgist. Dr. C. H. Lord is superinten-
dent and F. H. Lord, assistant superintendent.The Young America has a shaft down sixty
feet perpendicularly and crosscut to ledge.
They are now drifting on the vein with the face
of drift in ore of high grade, of red oxide. In
the same claim a tunnel 160 feet long crosscuts
the ledge and drifts each way have been run on
ledge. The ore is green carbonate, and black
sulphur, assays of which have run as high as
\$627. On the same claim are four other
shafts for the various conveniences of air and
development.They are working now about sixty-five men
of whom twenty-five are Mexicans. Most of
the work is done by contract at eight dollars per
foot, for a depth of fifty feet from the surface.
This property, a new starting up, promises a
good report to all concerned, and especially to
the stockholders. Several very fine photo-
graphs of the mine and the region around it
have been made.

Notes from Eureka, Nevada.

[From Our Regular Correspondent.]

EDITORS PRESS:—I do not remember when
Enreka (in town) has looked as dull as it does
at present. It seems as if a thunder cloud had
burst upon it. The mines that we have been
looking to for support for the past ten years
are no longer sending out the streams of bullion
that formerly made them two of the best mines
in America. The men are not employed upon
Ruby hill in as large numbers as they were in
the more prosperous days.

Four Dollars per Day

For a miner is, unhappily, not always to be had
for the asking. Miners, in fact, are now often
willing to take even chances with the mine
owners underground, and are less apt to lose
their hard-earned money by stock gambling.
These are facts worthy of consideration. Cap-
italists who are afraid to pay miners at the rate
of \$4 per day can find men willing to take a
share in the risks for a share in the profits.
Men who have been spending their earnings in
paying miners \$4 per day and quit broke, have
discovered that it does not require extraordinary
sums of money to develop their mines. Many
properties in this district that were formerly
considered only good for rich men to own, it is
now found can be operated with profit by poor
men. And this is being done, through a change
worked by the failure of the Albion.

The Frankie Scott Consolidation

Of mines on Prospect Mountain, were lately
leased to a party of miners who agreed to work
the ground on shares. So long had the mine
been lying idle, the bottom of the main incline
was filled almost chin deep with rats' nests, but
a small vein of ore had been followed from the
surface several years ago, which was then
thought barely sufficient to pay for sinking on
any deeper, but now appeared good enough to
take chances on. The lessees had not worked
in the ground longer than a week when the
vein opened out to a foot thick. The ore found
is very rich, some of it being full of horn sil-
ver. It will average from \$200 to \$300 per ton.
It is quite lately that a rich strike was made in
the Antelope mine adjoining the Frankie Scott.
These mines lie to the south of, and only a
short distance from the Enreka tunnel, and the
Alexander company's ground. The Enreka
tunnel is looking well as usual. The new
hoist is in place and ready to run. The Addi-
son chamber which is about sixty feet easterly
from the new engine shaft is looking better than
ever, showing signs of growing stronger with
depth. The same may be said of the carbon-
ate vein, which appears to be making into a
regular fissure.

The Albion Mine,

On Ruby Hill, is very quiet looking at present.
I was down in it yesterday, the first time
for nearly four months. Then it looked well,
and there was considerable ore in sight, but
it appears now that there was not sufficient at-
tention paid to prospecting the mine while the
ore was being extracted. As a son of Erin re-
marked, "The devil's the mather wid the mome,
but it's top-heavy." The money that should
have been expended for development under-
ground was spent in making unnecessary im-
provements upon the surface.Matters are being remedied as best they can
be. The miners' liens have all been paid up.
The bullion that was on hand at the time the
works were closed down has been marketed.
The ore from the bins is being shipped to the
Enreka Con. furnaces. There are miners un-
derground at work only where needed. There
are four miners taking out ore on tribute in the
Mammoth cave.I noticed particularly that there is ore mak-
ing downwards underneath the big chute, and
this is well worthy of note, when taken into
consideration the fact that in the Uncle Sam
crosscut, on the 335 level, is a vein of iron ore
which there are miners now employed in ex-
ploring. At the top of the raise the appearance
is encouraging, for the iron is the next thing to
ore, and it presents the same appearance as the
iron in the chambers that have been worked
out. Between the two points there is room for
a fair sized body of ore to make, probably about
225 feet on the dip, and 120 feet in vertical
depth. In the east upraise and October cave
are six men taking out ore on day's pay. In one
place there is very good looking ore, about five
or six feet in thickness, and there is a chance
for this to improve. There are two men taking
out ore on tribute from the top of the June

(CONTINUED ON PAGE 297.)

Silver Milling in Arizona.

While California has the credit of being the leader in the matter of gold mining appliances, Nevada bears a similar reputation with regard to silver. Experiments in every possible direction were made on the Comstock, where there was plenty of money to spend for them and plenty of enterprising men to carry them out. The experience of these many years is now being taken advantage of in newer regions, and fewer failures are chronicled than formerly.

Of course, in all new camps there have to be greater or less changes, made according to the nature of the ores and the character of the appliances at hand. The processes of working silver ores, in particular, have been carefully studied, and every possible economy has been practiced to make the mines more profitable.

In Arizona and New Mexico, where many new mills have been put up within the past few years on newly-opened mines, the companies have been able to obtain the very last appliances of all kinds, and their mills, therefore, embody all the latest improvements. They can

attained. The mineralogical and chemical constituents of the ore, and its physical properties, throw a flood of light upon the success or failure of a process. Figures representing totals I have subdivided as much as possible, so that the cost per ton for labor, castings, chemicals, etc., are apparent. Unless all these factors are known, no accurate comparison can be drawn, since in this branch of metallurgy, more perhaps than in others, the weakness of any one link in the chain of operations demoralizes the remainder. That it costs \$10 to mill in one locality, and \$5 in another, is, in itself, no criterion of the quality of work done. But when these costs are referred to a standard, or when several mills are working on the same character of ore in the same district, and the conditions are known, losses, errors, etc., may be easily detected and remedied. As a standard, the condition existing in any district can be taken. The cheapness with which the ores of the precious metals have been treated of late years in remote portions of our western Territories is remarkable. The handling of very low grade ores has been made possible, and the cost of beneficiating the same has been reduced to figures that will permit of working ore bodies which, only a few years ago, were excluded from the category of paying investments.

The Harshaw Mill.

The mill of the Harshaw mining company,

are composed of round bars of iron, one and a half inches in diameter, fourteen feet long, spaced two inches apart, and inclined at an angle of 32°. Rectangular bars set on edge are preferable to round bars, not being so liable to clog. Such screens are a material item of economy where large amounts of ore are handled, for, when placed so that the wagons can be unloaded over them, the finer material is separated from that which requires crushing, and the larger pieces alone require further handling, since what passes through the bars falls through chutes directly into the ore bins. It seems superfluous to add that wherever the expensive labor of the west can be advantageously replaced by automatic contrivances, it should be done, especially in the reduction of low grade ores; yet how often is this simple axiom ignored!

On the crusher floor, the lump ore, rolling down over the screens, is fed into a rock breaker of the "Eclipse" pattern, and reduced to pieces about the size of a hen's egg. This breaker is in operation ten hours a day, crushing in that time sufficient material, inclusive of that passing through the screens, to supply the stamps for twenty-four hours.

On the dump and around the crusher, four or five Mexicans are employed, whose wages are from \$1.50 to \$2 per day.

The ore bins, placed immediately below the

Stem.....	465 pounds.
Shoe.....	122 pounds.
Head.....	20 pounds.
Tappet.....	110 pounds.
Total.....	837 pounds.

They are run at ninety drops per minute, and fall six inches. A greater drop was experimented with, but it was found that the heavy stamps crushed through the light material and expended the additional force acquired to the detriment of the wearing parts and mortar. The stems are fourteen feet long, and three and one fourth inches in diameter, with nine and one half inches between centers. The shoes are of white iron, and last on an average eighty days. The dies which are of the same material, weigh 107 pounds. Ten double-armed cams, with a sweep of thirty-five inches, are keyed on to a cam shaft fifteen feet long and six inches in diameter, which has three bearings, each of thirteen and one half inches. The stamp-heads are of tough cast iron, with wrought iron bands, shrunk on at bottom and top, but in this case the bands used are too heavy, leaving only a small ring of cast iron intervening between the shank of the shoe and the band, which has a contrary effect to that desired, and weakens rather than strengthens the head. The discharge from the mortars is single, eleven inches high, through a number three vertically slotted screen of sheet iron.

PLAN OF SILVER MILL.

SETTLER FOR SILVER MILL.

accordingly do very good work indeed. All mining men are interested in the facts, resulting from the experience of every day work, and are glad to see metallurgists give others the benefit of their experience. We are pleased, therefore, to be able to present to our readers a paper on the subject of "Silver Milling in Arizona," by W. Lawrence Austin, Ph. D., Charleston, Arizona, which was read at a recent meeting of the American Institute of Mining Engineers:

It has been suggested to me that some data, bearing on the treatment of silver ores in south Arizona, would be in accord with the objects of the present meeting. I have, therefore, made a few notes, gathered from practical experience at some of the best known works of that district. Presuming the general arrangement of a silver mill to be familiar to members, the subject having been repeatedly brought to the notice of the Institute, it is my aim in the following description of the modus operandi at the different mills to which I would invite your attention, to give simply such salient points of the apparatus as have a direct bearing upon results, together with the cost of materials, labor, etc. I have gone somewhat deeply into detail in my descriptions of machinery, thinking that possibly some of our members engaged in this branch of the profession might find something of interest among them. In an industry such as silver milling, where the various works are scattered over a vast extent of territory, and the conditions under which results are obtained are subject to the greatest variations, it is essential to go into rather minute details in describing plants, processes, etc., in order to afford a clear idea of the operations. Not only should results be given, but also the means by which such are

situated in the pleasant little mining town of the same name, in the midst of the Patagonia mountains, southern Arizona, recently completed its first working year, after a twelvemonth of uninterrupted operation. The results attained reflect credit on the management, when the high price which labor commands in that remote quarter, and the distance from sources of supplies are considered. At that time the nearest railroad station was Pantano, on the Southern Pacific, so that all material for the mines and mills had to be hauled by wagons more than sixty miles, over a road that, in the rainy season, was almost impassable for heavy freight. The surrounding country is well wooded, mesquite, scrub oak and juniper all being found within easy access of the mill. The supply of water, however, is limited. I am indebted to Mr. Covington Johnson, the late superintendent, for the opportunity of examining in detail the workings of the system in use at Harshaw. The ore of the Hermosa mine, which alone is treated in the mill, is typically "free milling." Horn silver, green when first taken out, but darkening in color when exposed for any length of time, is scattered through a gangue consisting of decomposed fragments, apparently broken from the enclosing porphyritic wall rock, in which quartz, clay, hydrated oxide of iron, and black oxide of manganese are prominent features. It is readily friable, the stamps crushing an average of five tons per head in twenty-four hours, and occasionally as high as six tons have been run through.

The ore is hauled from the mine to the mill down a heavy grade of something under a mile by contractors, at a cost of fifty cents per ton. It is weighed at the mill—the weigher's wages are \$4 per day—and dumped over coarse screens. These screens, commonly known as "grizzlies,"

crusher, have a capacity of 200 tons. In designing a mill, it is always well to give such bins the greatest dimensions practicable, as they are often called upon to act as reservoirs in case of repairs being made on the rock breaker, or of accidents at the mine or on the road. When possible, they should be made to hold two or three days' supply of ore for the mill. From the bins the ore passes through chutes into automatic feeders which serve the stamps. Such chutes are quite short, and provided with a gate to regulate the supply issuing from the bins.

The self-feeders are of the "Hendy-Challenge" pattern, and give perfect satisfaction. This mill was originally fitted out with the "Eclipse" feeders, but after a trial they were replaced by the present "Hendy."

The Batteries

Are arranged back to back, as shown in the accompanying plan. Ten stamps are placed on either side, with the ore bins between them, the latter being built on to the battery frames, and the whole structure is thoroughly braced and bolted together.

Such an arrangement affords additional stability, and reduces, in a measure, that vibration which is so trying to the machinery, as well as to the man whose duty it is to attend to this department; on the other hand, its main drawback is that the "battery feeder" is obliged to exert himself more than is otherwise the case in order to watch over both sides. The batteries are four in number, each of five stamps, crush wet, and have an average capacity of five tons to the head. They are served by two men—wages \$4.50 per day—each of whom stands a twelve-hour shift. The stamps weigh over 800 pounds, the weight being divided as follows:

The actual discharging surface, deducting that covered by the wooden framing, is 479 square inches. The slots are one half inch long and one thirty-second of an inch wide. There are 9.6 of these slots to the square inch of screen surface. The top of the screen is inclined outward ten degrees from the perpendicular. The mortars are fifty inches long, inside measurement, and are provided with a double discharge, but it was found advisable to stop up the rear opening, partly owing to lack of water, partly because when a single discharge is used the screens are less liable to become stopped up. This was accomplished by blocking up with woodwork quite close to the stamp-heads, facing the whole with one half inch iron to prevent rapid wearing away. The closer the iron plate is brought to the stamps, the better are the results obtained. By this means, the splash caused by the falling stamps is thrown forcibly forward, the screens are kept clear, and the discharges are increased. While both discharges were open, the rear one passed more material than the other.

From the Batteries, the Pulp

Runs through laundries to a separating hopper, in which the coarse sand is separated from that already sufficiently fine for amalgamation. This apparatus is a simple funnel, with a partition at the side, so arranged as to direct the stream of pulp downward, and allow the sand to settle and discharge from the bottom, while the finer material rising on the other side of the partition passes through an overflow and laundries into the pans. The sand is run into separating pans. Each line of pans is connected throughout by piping, placed seven inches below their tops, which allows the pulp to flow on uninterruptedly, every pan in turn being filled, discharging into the next. The sand which is carried from

the bottom of the separator into the first pan of the series is ground in that and in the next following, and joins the lighter material coming from the overflow of the separator in pan number three. By this means all tank shoveling is obviated, the pulp being brought into the amalgamating pans in fit condition for treatment with quicksilver. It has not yet been satisfactorily proven that all milling ores will equally well admit of this easy solution of the tank difficulty, but, where it can be used, the large labor saving in time and money to be gained by this simple expedient is apparent. In the case under consideration, the ore being entirely free from "base," and the gangue having a light specific weight, the conditions are very favorable for this mode of treatment.

The Amalgamation

Is attended by two amalgamators—wages \$5 per day—and by two helpers—wages \$4 per day—working twelve hour shifts. The pans are of the ordinary flat bottomed "combination" type, as shown in the accompanying sketch. They are five feet in diameter, three feet four inches high, have cast-iron sides, and taper up from the bottom. The millers make sixty-eight revolutions per minute, and are lowered in the first five pans of the series. As the pulp proceeds down the line, and is subjected to the grinding action, the wear of the shoes and dies is lessened in each succeeding pan. There are eight shoes and eight dies to a set, weighing 1504 pounds. In the first two pans, where most of the grinding is done, the life of a set varies from thirteen to eighteen days, whereas in No. 5 pan they last several months. In the last three pans the millers are raised and only serve as stirrers. The pulp is heated to a scalding temperature by live steam introduced directly from the boilers. It requires about four hours for the pulp to pass through the eight pans, and 200 pounds of fresh quicksilver are charged into each of the last six pans every hour, the old charge being previously drawn off into settlers through inverted siphons, which are closed before the introduction of the new. The greater part of the amalgam accumulates in No. 3 pan, which is cleaned out every morning. Some amalgam always manages to work back into the first two pans, and is found there in the monthly clean up, although no quicksilver whatever is introduced into them. Some experiments were made to determine whether or not the amalgamation could be conducted cold, and it was found that the amalgam, instead of accumulating in any one pan as before, was pretty evenly distributed throughout them all. This illustrates the part which heat plays in amalgamation, for, although the percentage worked to was in both cases about the same, still the time which it was necessary to keep the pulp in contact with quicksilver is greatly increased when steam is not used.

The Settlers

Are placed in the usual manner below the pans, one to every pair of the latter. Like the pans they are constructed entirely of iron, eight feet in diameter, three feet deep, and make thirteen revolutions per minute. The shoes, as shown in the accompanying sketch, are placed so as to throw the pulp downward, and at the same time toward the center. They are four in number, one on each arm, and are raised one fourth of an inch from the bottom. As the pulp is already quite thin, very little clear water is used to dilute it further, but the temperature is considerably lowered by passing cold water through a spiral pipe attached to the sides of the first settler. The settlers are connected in a similar manner to the pans, but in their case the piping is given a down grade, so that the end settler is never more than half full.

The tailings after leaving the settlers fall into wooden agitators, which make twenty revolutions per minute, and are shovelled out once a month. From then the tailings run to waste, carrying an average value of four dollars per ton. Only

Small Quantities of Chemicals

Are used in the pans—a little cyanide of potassium, with a view of cleansing the quicksilver, and some caustic lime to collect any that may become floured. These are fed into the pans automatically, the cyanide of potassium into No. 3, and the lime into No. 7. Altogether only fourteen pounds of the cyanide and 120 pounds of lime are used to 100 tons of ore. In order to determine how much lime is to be added, a dipper full of pulp is taken from No. 8 pan and washed with a gentle stream of clear water, until only the quicksilver remains. This is usually in the form of small globules. If, on gently shaking, these readily unite, all is well, but should they refuse to do so, it shows that not enough lime has been used. Owing to the entire freedom of the ore from "bases" of any nature, the amalgam produced is remarkably clean; still a portion of the iron from the wear of shoes and dies finds its way into the amalgam, but is easily gotten rid of in the clean-up pan. It usually requires four hours to clean up a charge of amalgam. About 1000 pounds is put into the pan and thinned with fresh quicksilver, then heated by live steam and stirred for a couple of hours. The impurities rising to the surface are wiped off with a sponge, and about equal quantities of salt and sulphuric acid are thrown in, and the whole is stirred for an hour. No difference in the appearance of the amalgam is effected by these chemicals, but on the addition of caustic lime a black scum immediately makes its appearance. This is washed off by allowing a

current of clear water to flow through the pan. The amalgam is then taken out and piled on straining sacks.

The Retorting and Melting

Is carried on in a separate building. One man attends to both—wages five dollars per day. The retorts are five feet three inches long over all, one foot inside diameter, and weigh 1,170 pounds. They have a central discharge, and hold when full 800 pounds of amalgam. A cord of scrub oak suffices for retorting seven or eight charges. The firing lasts about five hours, the amalgam retorting to one sixth.

The furnaces for melting the retorted bullion are 15'x16', and 21' deep, inside measurement. Eight bushels of a very inferior charcoal are used for melting a bar of 2,000 ounces. A No. 70 graphite crucible is used in this melting. The bullion averages .995 fine, or more. All quicksilver used in the mill is pumped up to the pans by the hydraulic pressure system, a pipe connecting the quicksilver reservoirs with the mud-drums of the boilers.

The motive power of the mill is furnished by a 200 horse-power engine—cylinders 42"x20"—run at sixty revolutions per minute. Two engineers are employed—wages \$5 and \$6 per day, respectively.

Four tubular boilers—15' 6"x54"—carrying eighty-five pounds pressure supply the steam, and require sixteen cords of the assorted wood of the country per day. Three firemen—wages \$3.50 per day—and two wood-passers—wages \$2 per day—attend the boilers.

All the water used is pumped from the gulch below by two Cameron steam pumps (No. 6) through a 2" pipe. The boiler which supplies these pumps requires eight cords of wood per week; two engineers—wages \$4 per day—look after the pumps.

The cost of reducing a ton of ore at these works, estimated from a run of 2,643 tons, was \$3.12, but this does not include the hauling, stated above to cost fifty cents per ton, or the general office expenses. This amount is subdivided as follows:

Cost Per Ton of Ore.

Labor.....	\$1.23
Supplies.....	1.82
Assaying.....	0.07
Total cost per ton.....	\$3.12

The cost of labor, per ton of ore, in the various departments, is as follows:

Crushing.....	\$0.26
Amalgamation.....	0.20
Power, pumps, and repairs.....	0.40
Foreman, melter, etc.....	0.37
Total.....	\$1.23

Cost of Materials Per Ton of Ore

Quicksilver.....	\$0.42
Chemicals.....	0.07
Castings.....	0.29
Illumination and lubrication.....	0.07
Fuel.....	0.78
Supplies.....	0.19
Total.....	\$1.82

The consumption of wood, per ton of ore, was 0.15 cord, and of quicksilver 0.96 pound.

The Mills at Charleston.

Most of the mills working the ores of the Tombstone district are distributed along the line of the San Pedro River, at an average distance of ten miles from the mines at Tombstone.

The works at Charleston, of which I am manager, are the property of the Tombstone Mill and Mining Company, and are under the general supervision of Professor John A. Church.

These mills were originally intended for dry crushing, and were provided with rotary dryers, automatic roasters, and all the necessary paraphernalia for a chloridizing roasting, as it was expected that the ore would become base as depth was obtained in the mines. But, contrary to expectation, the deposits retained their free milling qualities as they went down, and the furnaces were never brought into requisition. Upon ascertaining the true character of the ore under treatment it was decided to change the batteries to "wet crushers," in order to increase their capacity, which alterations injured the symmetry of the plant, and left it working at some disadvantage over what might have been had such a change been foreseen in the original designs.

The smaller of these mills (the Pioneer mill of the district), was originally built by the company as an experiment, and constructed with an eye to economy; a wise precaution, as many have learned to their cost who have anticipated developments in their mines by the construction of expensive reduction works. This mill was originally fitted with ten stamps, four pans, and two settlers, and run by a Lefel turbine, water being brought in a ditch from a dam about one mile up the river. Later, in order to increase the capacity, five stamps, two pans, and a settler were added. To run this additional plant up to the necessary speed required more power than the turbine could furnish, so an engine was purchased as an auxiliary. The second and larger mill was subsequently acquired by the company. As both mills run on ore from the same mines and the processes are identical, a sketch of one mill will suffice for both.

It is to be regretted that owing to the separation of the mills, consequent doubling of the payroll, and increased expenses from every source, the cost of milling given below will be scarcely a guide to what could be done with a properly arranged plant. I do not hesitate to say that with altered conditions a reduction of 20 per cent. per ton in the cost of ore milled could be effected, the quality of the work remaining the same.

In the following hasty sketch, reference is had to the larger mill alone.

The Power is Furnished.

By a horizontal engine with Corliss bed and Meyers patent cut-off, making 70 strokes per minute. The cylinder is 16" x 36". This engine runs with remarkable smoothness, and is not shut down more than once in sixty days, and then only to afford an opportunity for cleaning out the boilers, in which, owing to the water used, a scale rapidly collects. These latter are tubular, 54" x 16", and carry steam from 90 to 100 pounds pressure. Farciot's patent pump and heater feeds them, pumping the water in at boiling-point. They consume on an average seven cords of mixed wood per day, costing \$9 per cord; black oak, white oak, willow, and pine being used indiscriminately. All the water for the mill is pumped a vertical height of 100 feet by a No. 5 Knowles steam pump, placed 200 yards from the mill, which readily supplies more than is consumed. Steam is carried to this pump from the mill boilers. The ore is brought down from the mines, a distance of ten miles, in wagons. These wagons are connected in pairs, weighing about 5 tons; they carry 14 tons of ore between them, and are drawn by sixteen mules. This hauling is done by contractors at \$3 per ton. The bottoms of these wagons consist of a series of pieces of plank, 6" x 2", laid crosswise, their ends resting on the framework of the wagon bed, so that, when removed one at a time, they allow the ore to drop out, and permit a rapid and easy unloading. It requires on an average twenty minutes to unload a pair of wagons constructed on this plan, and, as they are filled at the mines from self-discharging chutes, the driver has little labor in loading and unloading.

The ore is wheeled in barrows

From the Dump to the Crusher

Through which it all, coarse and fine, passes, no screens being provided. One of Hendy's breakers is used. The bottoms of the chutes leading from the breaker to the bins are, for a distance of 5 feet, made of 4" steel bars set 3" apart, allowing all the finer materials to fall through on to a shaking screen hung below. This shaker is provided with the same screens that are used in the batteries, and separates that portion of the ore already sufficiently fine not to need crushing, which is sent direct to the pans. This relieves the batteries materially, and decreases the amount of "slimes." By this simple contrivance the capacity of the mill was increased 5 per cent., or more, the amount depending on the fineness of the ore, and also on its per cent of moisture.

The batteries are fed from the bins by the "Hendy-Challenge" self-feeders, which here, as elsewhere in my experience, give entire satisfaction. The stamps are 20 in number, drop 100 times a minute, fall 61", and when freshly shod, weigh about 750 pounds, the weight being divided as follows:

Stem.....	340 pounds.
Head.....	200 pounds.
Tappet.....	90 pounds.
Shoe.....	120 pounds.

The die weighs about 85 pounds. Some of the stamps carry extra tappets, bringing their weight up to 800 pounds and over. The shoes have an average life of one month, and when worn out weigh about thirty-five pounds.

A Novel Feature of these Batteries

Is the arrangement of the guides; instead of being grooved to receive the stem, square recesses are cut, into which wooden keys are fitted, so that the grain of the wood is parallel to the motion of the stem, instead of across it, as is usually the case. With such an arrangement, the guide boards themselves are subject to no wear, the keys being easily taken out and replaced. This plan might be advantageously adopted where light stems are in use which are liable to spring, and in such a condition saw out guide boards very rapidly. But when stems of 3 1/2"-3 3/4" are used, they present no advantages over the old plan. The mortars have double discharge, but the rear discharge has been blocked up with wood faced with iron plates, as close to the stamps as practicable. The average product of these batteries during the first six months of the year, including stoppages, has been two and nine-tenths tons of medium hard rock to the head of stamps, per day of twenty-four hours, crushed through a 30-mesh screen. Various screens have been tried, but the best results have been obtained from Russian iron screens, vertical slotters with a "burr" on the inside.

From the batteries the pulp goes into settling tanks.

The Pans,

Eight in number, are flat-bottomed, five feet in diameter, three feet high, and have wooden sides of Oregon pine curls, two and one half inches thick. The die is a solid cast-iron ring one and one half inches thick, weighing 750 pounds, and occupying most of the space between the cone and sides. It is fastened in with Portland cement. The muller, weighing 570 pounds, carries eight shoes weighing collectively, 816 pounds. Each pan is provided with three wings shaped like a reversed plowshare. The settlers are nine feet in diameter, with iron mullers shod with wooden shoes six inches high. On the average a ton and a half, dry weight, of sand and slime are put in a pan for a charge, and the time required for amalgamation varies from three to five hours after charging the quicksilver. Repeated experiments have shown that little is gained by running the pans over four hours. The same ore, treated side by side under the same conditions in pans, running respectively on four and six hour charges, gave a gain of one per cent. in favor of the six-hour

charge; but this slight advantage did not compensate on low grade ores for the limited capacity of the pans. Tests made on pulp while undergoing amalgamation showed that one hour after charging quicksilver, 74.66% of the silver was already taken up, and that in the succeeding hours 76.26%, 77.74% respectively, until the end of the fourth hour, when 81.04% was found to have been extracted.

After that period, nothing material was gained by prolonging the operation. For a long time, owing to the excellent quality of the ore, no auxiliaries other than steam and the iron of the pans themselves were needed by the quicksilver to effect amalgamation. Identical results were obtained with or without the use of chemicals. Little by little a change crept in, the milling percentage sank, the bullion became less fine, and sulphurets of the base metals made their appearance in the ore. Tests made with a view of determining the aid to be derived from the use of bluestone and salt, showed that in ore containing only seven per cent of its silver in the form of chloride, eighty-seven per cent of the silver present could be brought into combination with that element by the aid of these two "chemicals." The remaining thirteen per cent was apparently shut up in the base sulphurets and carbonates, and could not be chlorinated in the pans.

The Result of a Series of Experiments.

With these and other reagents, led to the adoption of 150 per cent of bluestone and 500 per cent of salt, the amount of silver in the ore being taken as 100 per cent, and by this means the milling percentage was brought back to its former standing. Still the bullion resulting left much to be desired. The question then resolved itself into this, how to make fine bullion from very base ores, and at the same time to keep up a satisfactory milling percentage.

Three methods suggested themselves, either to prevent the amalgamation of the base metals on the pans, or if that proved impracticable, to eliminate them from the amalgam before retorting, or during the melting. Although several metals were taken up by the quicksilver, in varying quantities, and so found their way into the bullion, still the only one that caused any serious trouble was lead, which was reduced by the action of the pans and amalgamated as readily as the silver itself. A noticeable feature in regard to the basing of this bullion was, that it became serious at the same time that wulfenite appeared in considerable quantities in the ore. Whether this mineral was the prime cause of the trouble I am not prepared to say; but we did not have the same difficulty when the percentage of lead was much higher in the ore, but in the form of cerussite or galena.

The ore was crushed through a screen corresponding to a 35-mesh wire cloth, and subsequently ground for one hour in the pans. By giving up the grinding in the pans, and by using finer screens in the batteries, but little of the lead was taken up; and by the use of lime, etc., in cleaning the amalgam, as already described above, the bullion was brought up to .970 fine; the remaining base, being principally copper, resulting from the bluestone used, was not of sufficient importance to extract. The extraction of copper, even after it has been amalgamated, presents no difficulties, as has been successfully demonstrated on a working scale at the tailing mills on the Carson River.

The Ores of the Tombstone District.

Carry a varying amount of gold, which in some bases is visible; but in others it only makes its presence known by the assays. At Charleston it is not positively known in what form this metal occurs, as it is never visible. Assays for the first six months of this year show that only 43 per cent or the total gold value of the ore was saved. This value, however rarely reaches two dollars to the ton. The amalgam is retorted in 15-inch top discharge retorts. About four cords of willow wood are consumed to the ton of amalgam. The firing lasts five hours, and the charge varies from a ton upward.

For bullion averaging .938 fine the loss by volatilization and skimming averages 7.55 per cent and the time required averages three hours twenty one minutes. The average weight of the bars is 2711 ounces, which require 43 pounds of charcoal and 20 pounds of coke. The average cost of milling for the past five months has been \$4.90 per ton. This amount was subdivided as follows:

Fuel.....	\$1.05
Chemicals (including quicksilver).....	0.77
Lubrication.....	0.04
Illumination.....	0.03
Castings.....	0.33
Supplies.....	0.16
Labor.....	2.52
Total.....	\$4.90

Cost of Labor in Reducing one Ton of Ore.

Crushing.....	\$0.52
Amalgamation.....	0.56
Power, pumps, etc.....	0.47
Foreman, etc.....	0.87
Tailings pit.....	0.11
Total.....	\$2.64

The loss in quicksilver to the ton of ore milled varies according to the grade and character of the ore, but averages about 1.3 pounds. About 0.11 cord of wood and 1200 gallons of water are consumed to the ton.

* This table has reference simply to a single month's run, or, what is the same thing, to the working of 1730 tons of ore.

Superstitions About Gems.

There are many curious superstitions and fancies concerning precious stones, and one of them, which, as it is elegant and fanciful in its absurdity, is perhaps worthy of mention in this place, includes almost the whole group of gems used for ornament. It is a Polish idea that every human being is born under the influence of some destiny, that the month of his nativity has a mysterious connection with this, and that when it is desired to make a present to one greatly valued and loved, a ring should be offered containing a gem expressing some such quality as the destiny would indicate. Each precious stone thus has reference to some particular month; and the following list is copied from a memorandum drawn up by a Pole many years ago:

January.—Hyacinth or garnet. Constancy and fidelity in every engagement.
February.—Amethyst. Preserves the wearer from strong passions, and insures peace of mind.
March.—Bloodstone. Courage and success in dangers and hazardous enterprises.
April.—Sapphire or diamond. Repentance and innocence.
May.—Emerald. Success in love.
June.—Agate. Long life and health.
July.—Carnelian and ruby. Forgetfulness, or cure of evils springing from friendship or love.
August.—Sardonyx. Conjugal fidelity.
September.—Chrysolite. Preserves from or cures folly.
October.—Aqua-marine or opal. Misfortune and hope.
November.—Topaz. Fidelity and friendship.
December.—Turquoise or malachite. Brilliant success and happiness in every circumstance of life.

Another curious superstition concerning gems is that the twelve Apostles were symbolized, each under some one. The list is curious, but one can hardly see the meaning of the allusion. It is as follows:

St. Peter—Jasper; St. Andrew—Sapphire; St. James—Chalcedony; St. John—Emerald; St. Philip—Sardonyx; St. Bartholomew—Carnelian; St. Matthew—Chrysolite; St. Thomas—Beryl; St. Thaddeus—Chrysoprass; St. James the Less—Topaz; St. Simeon—Hyacinth; St. Matthias—Amethyst.

The stones in this list are sometimes called the Apostle gems.

Indiana Capital in Arizona Mines.

[From our Traveling Correspondent.]

The Copperopolis Mining Company.

A few months since Wilson Collier, one of the enterprising Arizona prospectors, was in possession of several mining locations in Castle Creek district, about sixty miles from Phoenix. This is a genuine copper mining region. His showing of croppings was so favorable as to induce Thos. H. Kirby, W. B. Kline, Jas. Boice, Jno. M. Kirby and Geo. Kirby to furnish the capital requisite to develop the mines, for a half interest in the same.

So far everything has developed very satisfactory to all parties and a fully organized mining company is now carrying on the further developments. The capital stock issued 460,000 shares, with a provision to issue 40,000 more shares for additional working capital if required—the 60,000 already issued is sold for working capital but bought mostly by the stockholders. The other 400,000 shares are owned equally by the Indiana capitalists and Mr. Collier, that is, Mr. Collier has 200,000 shares in the company's stock, known as the Copperopolis Mining Company.

The officers are, W. B. Kline, President, and Thos. H. Kirby, Superintendent. They have been working lately twenty-five to thirty men on mines and roads, getting everything in readiness to receive the copper smelter, which was loaded on wagons at the railroad depot at Maricopa station. They got their complete outfit all at the Pacific Iron Works, San Francisco. They send with the furnace a thorough practical machinist and metallurgist to set up and initiate the operations.

The business management seems to be one of practical good sense, with a thorough management on a cash basis.

The ore contains such a percentage of iron as is supposed to enable them to flux with small amount of lime for flux. They will use Trinidad coke, and also some English coke from San Francisco. They have on Castle Creek a splendid site for smelter, making an easy down grade for their own ores, and accessible for custom ores.

B. W. CROWELL.

Phoenix, April 17, 1883.

Know

That BROWN'S IRON BITTERS will cure the worst case of dyspepsia.

Will insure a hearty appetite and increased digestion.

Cures general debility, and gives a new lease of life.

Dispels nervous depression and low spirits.

Restores an exhausted nursing mother to full strength and gives abundant sustenance for her child.

Strengthens the muscles and nerves, enriches the blood.

Overcomes weakness, wakefulness, and lack of energy.

Keeps off all chills, fevers, and other malarial poison.

Will infuse with new life the weakest invalid.

37 Walker St., Baltimore, Dec. 28th. For six years I have been a great sufferer from Blood Disease, Dyspepsia, and Constipation, and became so debilitated that I could not retain anything on my stomach, in fact, life had almost become a burden. Finally, when hope had almost left me, my husband seeing BROWN'S IRON BITTERS advertised in the paper, induced me to give it a trial. I am now taking the third bottle and have not felt so well in six years as I do at the present time.

Mrs. L. F. GRIFFIN.

BROWN'S IRON BITTERS will have a better tonic effect upon any one who needs "bracing up," than any medicine made.

TATUM & BOWEN,

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphures, arseniures, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequaled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quick-silver. Illustrated. 156 pages. A valuable and carefully written work. Post-paid, \$5. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four woodcuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

THE EXPLORES' MINERS' AND METALLURGISTS' COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 pages and 83 Engravings. Price, bound in cloth, \$10.50. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

Mining Companies.

Persons interested in Incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Buchanan Gold Mining and Milling Company.—Location of principal place of business, San Francisco, Cal.; location of works, Tulumene, Tulumene county, Cal.

Notice is hereby given that, at a meeting of the Board of Directors, held on the 3rd day of March, 1883, an Assessment (No. 2) of Five (5) Cents per share was levied upon the capital stock of the Corporation, payable immediately. In United States gold coin, to the Secretary at the office of the Company, Room 3, No. 121 Post street, San Francisco. Any stock upon which this Assessment shall remain unpaid on the 21st day of May, 1883, will be delinquent, and advertised for sale at public auction and, unless payment is made before, will be sold on FRIDAY, June 1, 1883, to pay Delinquent Assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, J. A. MULLIVAN, Secretary.

OFFICE—Room 3, 121 Post Street, San Francisco, Cal.

ASSESSMENT NOTICE.

Seaton Gold Mining Company.—Location of principal place of business, San Francisco, California; location of works, Drytown, Amador county, Cal. Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of April, 1883, an assessment (No. 2) of one and one-half cent (1½) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, A. Warner, at his office, No. 224 Kearny street, room 2, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of May, 1883, will be delinquent and advertised for sale, at public auction, and unless payment is made before, will be sold on Tuesday, the 5th day of June, 1883, to pay this delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, A. MARIN, Secretary.

OFFICE—Room 6, 528 California street, San Francisco, California.

NOTICE TO CONTRACTORS.

Sealed proposals will be received by the Brandy City Mining Company until May 1, 1883, to run a bedrock tunnel to its mining lands, situated at Brandy City, Sierra County, Cal., near the town of Camptown, Yuba County. Said Tunnel to be about 3,000 feet long, 6 feet wide and 8 feet high, with a grade of 5 inches to every 12 feet. Water Power furnished. Responsible parties only need apply. Privilege reserved to reject any and all bids. For further particulars inquire of

Attention, Boiler-makers and Engineers!

Just Out! The Best Work of its Class Published!!
The Theoretical and Practical Boiler-maker.
By SAMUEL NICHOLS, Foreman Boiler-maker, Embrace all details of Geometry and Orthographic Projection as applied to Boiler-making; also to make, draw, design, and set out all kinds of Temple Work, as Ellipses, Cones, Truncated Cones, Oblique Cones, Frustums of Cones, Chimney Bottoms, Cylinders, Cylinder and Cone, Cylinder and Sphere, Cylinder connected with Curved Tubes, Cylinder and Angular Tube, Cylinder with Spiral Staircase, Hip Roof and Cylinder, Tubes, Angular Tubes, T Tubes, Taper Tubes, Curved Tubes, Conical Tubes, Double Conical Tubes, Flange Joints, etc., etc., of every kind, illustrated with 14 diagrams, including a full solution of all the problems relating to Boiler-making. The Cylinder, its sections, penetration, and development. Welding and Construction, Drilling, Punching, Riveting, Single and Double Riveted Lap and Butt Joints, with Stitches and Double Stitches. Diameter, Spacing, Strength, and Pitch of Rivets. Thickness and Pitch of Stays. On Locomotive, Marine, Cylinder, Multitubular, and Egg-shaped Boilers. Power of Boilers. Heating Surface of Boiler Tubes in square feet; the Lever Safety Valve, the Cylinder, the Sphere; Area of Fire Grates; Quantity of Steam required for an Engine; Flat Surfaces, Boiler Explosions; Practical Notes on Steam; Properties of Saturated Steam; Proportion of Boilers; Bursting pressure of Horizontal Wrought Iron Cylindrical Boilers; Collapsing pressure of Wrought Iron Cylindrical Tubes of varying thicknesses. Practical Rules, Instructions, and Measurements for Boiler-makers. Material for Boiler Construction; Weight, Strength, and Dimensions of Wrought Iron Boiler-plates and Iron Bars. Strength of Steel Plates, treatment of do.; Strength in Plates of different temperatures. Strength of Ropes and Chains; Properties of Metals; Weight of Wrought Iron Cylinders per lineal foot of any given diameter and thickness; Angle-iron Hoops; Diam. Circle and Area of Circle, with detailed calculations relating to Boiler Construction, to determine thickness of Boiler Heads, Cylinder Covers, etc. Measurement as applied to Boiler-making. Fuel Values. Combustion of Fuel, Evaporation of Water; Setting Boilers, Insulation, Boiler Scale Preventives, 35 kinds; Decimal Equivalents; Weight of Water; Expansion of Water; Squares, Cubes, and Roots; Fusing Points of Metals; Conducting Powers of Metals; Useful Definitions. Reference Tables (83 pages) for Boiler-makers, Engineers, Smiths, etc. 4 vol. 12mo, extra cloth. Bound price free to any address on receipt of \$2.50. Send for 125 page Illustrated Catalogue of 3000 Standard Books on every subject. Agents wanted, National Book Company, 73 Beekman Street, New York.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at very low rates and on easy terms. There are 12,000 acres at from \$3 to \$30 per acre, including pasturage, vine, fruit land and grain land. Will sell the whole tract at a great bargain. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

Canvassing Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation etc., to the publishers of this paper.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and Pacific Rural Press 252 Market St. Elevator, 12 Front St., S. F.

A New Street Railroad System.

Bridewell's Cable Road.

Most people on this coast have witnessed the operation of the cable railroad system in San Francisco, and are interested in new devices and improvements in that line. The Clay street cable road, the first built in this city, has been built ten years, and since that time there have been about nine roads built, and others projected. The working expenses are much less than horse-car roads.

R. F. Bridewell, of this city, has invented a new system of cable roads, and has six new patents and improvements, which he is about to introduce. They are described by the inventor as follows: First, the underground rail-bed; second, the automatic grip; third, the engine house machinery for propulsion; fourth, indicator and advertiser; fifth, the ways for turning corners and curves; sixth, the air brake and starter. The rail-bed is placed under ground, by making a channel of proper width and depth, in which are set iron frames about three feet apart, made with all necessary flanges for bolting the rails, which are under the surface about thirty inches, more or less. The gauge may be twenty-eight inches, more or less.

At the surface is placed two slot rails (as shown in Fig. 3), made like the letter L inverted. The rails form an even line on each side of the slot, which is laid even with the surface of the street. The trucks of the car run in the tramway, and the coaches above.

Every fourteenth frame is provided with a pulley for the cable to run on, over which is a man-hole, with a cast iron cover, bringing them about forty-two feet apart along the street. A pipe is run along the bottom of the tramway, which is connected with the water tank at the engine house, or the city main; on this pipe, under each man-hole, hand wheels, stop cocks and nozzles are placed, which are used in washing out all debris, as the bottom of the tramway is made like a sewer, and is connected with the same at all depressed places on the road. The pipe is arranged so as to connect with the furnace at the engine house, and during the winter, when the snow falls, the water will be drawn off and hot air forced through the pipes, to prevent the snow from freezing in the tramway. In the

or forward, the move is the same. The cars are also provided with other brakes.

The cars are provided with two endless bands, placed in the top of the car, which are made to

When the car is stopped on the curve, the cable goes straight through the grip, without touching the side of it. When the cars are started the grip will be closed on the cable, and

FIG. 6 - BACK AND FRONT VIEW OF GRIP.

receive cards, one half of which will have the names and numbers of all the cross streets to be crossed on the road. The others will be advertisements. When the street is to be crossed,

goes on as it would on the straight part of the road. The curves are turned as easily as the straight part of the road, as the cable is first pressed out of the groove of the pulley, and

R. F. BRIDEWELL'S CABLE RAILROAD SYSTEM.

tramway, on each side of the rails, are spaces for the use of all telegraph, telephone and electric wires. This is provided in order to take all wires and poles, as well as rails, out of the street.

To build the engine room, the street must be excavated and iron beams are placed, to be covered over with brick. The tramway is carried over the beams in a straight line. The propulsion is endless clamping jaws, upon the endless cable, with steam engine motor power. The cable is carried through the tramway by the clamping jaws, which open and shut automatically, grasping the cable very lightly, but will not let it slip. The jaws are lined with any kind of material that is suitable, and which will not injure the cable. (See Fig. 4).

The grip works automatically over all cross cable roads, without the aid of a driver. It can be stopped over the engine house, and started as readily as on any part of the road. It will cross its own cable, or any other.

The air brake is on the trucks. When the driver wishes to stop his car, he places his foot upon the treadle, and that releases the cable and engages the air brake, which stores up the force the car had while in motion, which is used in starting it, by shoving a lever the direction the car is to be moved. It will start the car either back or forward. The car has much force to be overcome in stopping. Whatever that force is, it is not lost. In starting, the brake is not dependent upon the stored air, but has a vacuum which is acted upon by the pressure of 14.7 lbs. to the square inch, and the lever is changed, so that one pound saved in stopping will give two in starting. The levers on the grip and air brake are always right-handed. It will make no difference if the car is turned around, or if it is to be run backward

the car comes in contact with a rack, which is placed on each side of every cross street, and that engages with a gear wheel in front of the trucks, and the wheel is turned around it, being arranged with a lever and a rod passing up through a pipe to the helts, draws up the hand and brings the name or the number of the street opposite an opening which is over the doors of the car. When the name of a street is to appear, notice will be given by the ringing of a bell. When the street is crossed, the name will disappear, and the next in order being an ad-

ARRANGEMENT AT CURVE.

vertisement, will present itself to be read by the passengers until the next street is reached, and so on, all day and night. As the lamp hangs in the center of the car, it will show as well by night as day.

Fig. 6 shows the curve, which is to a scale three times quicker than that ordinarily allowed to turn street corners. The curve is provided with a circle of wheels to carry the cable. The car trucks have a carriage, which is bolted to the trucks, and the grip works on the inside. The carriage has wheels on each side of it, and rollers at each end, for the cable to play against. When it starts around the curve, the cable is kept straight in the carriage, on the curve.

cars will have to be turned around at the end of the road by running them on a turn table. Where the side tracks turn out, the cable will have to run under a pulley to press it down, so as to let the wheel pass over the cable. Single rail tracks can be made much cheaper, as one rail can be used on the bottom, and have side wheels at the top. These roads, for country towns, can be made and operated on a very cheap scale.

It may not be out of place to insert a few remarks by the inventor upon the advantages that this system has over all other street railroads: The road-bed being under ground, the rails, which are made of steel, are not exposed to the weather, and the abuse by heavy wagons and drays abrading them. They are free from all mud, rocks or trash of any kind, and the cars will run much smoother, as the joints will remain even. The cars being low, and close to the ground, elderly people will be able to enter and leave them quite easily. The safety to pedestrians will be greatly increased, the wheels being under ground cannot possibly run over them. The cars are provided with indicators, showing all the names of the cross streets in large letters, over each door of the car. The power saved in operating, and the daily wear of the cable, is something that deserves notice by stockholders. The cost to build a road on this plan is much less than others. The rails are not required to be over eighteen pounds to the yard, in place of thirty-six or forty-five pounds, as now required for flat rails on the street. The advertisements will pay, and the space for wires is worth considerable. The corners and curves are turned without jarring or jerking them. The cars can run up grade around the curve; the contour of the street is never lowered or raised in order to obtain a momentum to carry the cars around them.

Further information can be obtained by addressing the inventor.

TITLE TO MINING CLAIMS.—In the case of the Pacific Coast M. and M. Co., against James Spargo et al. and L. Fick et al., Circuit Judge Sawyer has rendered an opinion holding plaintiff entitled to the mines and lands on Deer Creek below Nevada city from which it had been ousted by defendants. In December, 1874, certain parties entered at the United States Land Office lands which were afterward secured by patent and subsequently sold to plaintiff. Min-

FIG. 3 - SECTIONAL VIEW.

ing lodes were located and also conveyed to plaintiff. The defendants were charged with entering these lands by means of a tunnel beneath the surface, extending from a point outside the boundaries. The patent to plaintiffs contained the clause, "subject to any vested and accrued water rights for mining, agricultural, manufacturing or other purposes." When the patent issues, Judge Sawyer holds it covers everything embraced in the land to which no prior right attached. The two cases are similar and the decision is against defendants in each case.

SUTRO TUNNEL.—The total mortgage indebtedness of the Sutro Tunnel Co. is \$982,962.52, exclusive of interest, which on January 1 last amounted to \$234,181.80. During the past three years, 2,920 feet of the main tunnel have been retimbered. This ground stands very well and requires but little attention. But many of the timbers which were put in before that time are decayed and will have to be replaced during the coming year, including those within the 224 feet of heavy swelling ground near the Combination shaft connection. There are also about 600 feet of ground which is constantly swelling which should be retimbered and about 3,000 feet of track should be reggraded. The receipts and disbursements for the year to March 1 were as follows: For royalties, \$47,627.84; receipts under mortgage, \$39,040.00; other sources \$10,583; cash on hand, \$2,002.12; total \$99,212.96. The disbursements were \$98,077.63 for all expenses of operation.

COLONEL JACK HAYES, the well-known Texan ranger, and founder of the City of Oakland, in this State, died at his residence near Piedmont, Alameda county, Saturday last.

Metallurgy in Arizona.

Working Ores at the Silver King Mine.

[Written for the MINING AND SCIENTIFIC PRESS.]

Final is not so lively now as it was in the flush days of the Silver King mine, from which, and the connected works, it has always derived its chief support. The Silver King mine, though said yet to contain an immense body of ore, is far less rich than in former times, as is shown by the weekly reports, by the output, and by the greatly diminished reserve fund. The S. K. reduction works consist, at present, of twenty stamps and twelve Frue concentrators in operation, with a roasting and leaching plant idle. The concentrators are exported. Roasting and leaching were adopted a few years ago for the treatment of a portion of the ore which did not admit of concentration, on account of containing heavy spar. Prior to this, as at present, concentration alone was carried on.

The Ore Roasted was Rich, and otherwise well adapted to the leaching process. It was easily roasted in cylinder furnaces of the class known as the Pacific chloridizing furnace, but arranged with a fire-box at each end for the purpose of more equally heating all parts of the charge. The fire-boxes were used alternately, at intervals of from one to two hours, the unused one forming, for the time, a part of the flue. The roasting of a charge of five tons of ore, with about ten per cent of salt occupied from ten to fourteen hours. The character of the ore gradually changed until a charge of three tons required from twenty-four to forty hours roasting. At times it was impracticable to roast the ore well in the usual way, unless about seven per cent of sand were added. This gave very fair results, and by counteracting the tendency to sintering reduced the roasting time considerably. Another method was to roast without salt to complete oxidation, and then to chloridize by means of salt and copperas. This plan gave high solubility, and reduced the time of roasting a four-ton charge to twenty-five hours; but the roasted ore was leached with some difficulty owing to its not admitting of rapid percolation.

The Roasting was Very Costly.

As well be understood when I say, that on taking charge of the works, I found no less than nineteen men employed between the battery and the leaching vats, that is to say nineteen men engaged in drying, repulverizing, roasting and elevating from nine to ten tons of wet crushed ore per day of twenty-four hours. A cord of wood, costing from seven to eight dollars, was consumed per ton of ore.

The force was soon reduced to seventeen men, but no further diminution was feasible owing to the prevalence of the eight-hour system, and to inherent defects of the plant. The ore treated also was less rich than formerly. The presence of a large percentage of zinc blende caused a considerable loss of silver by volatilization amounting, despite the constant use of steam in the furnaces, to about eight per cent, to which was added a large loss by dusting during the repeated handlings to which the ore was subjected, and by deposition among the embers in the unused fire-box which formed the connection between furnace and flue.

Under these circumstances the treatment of this class of ore was discontinued, which caused a very material reduction in the working force of the mill, and a corresponding one in the amount of money disbursed monthly, which latter circumstance so disgusted the good people of Pinal as to induce some of the less wise among them to make a feeble and futile attempt to frighten the metallurgist from his post. The reduction of the reserve fund is partly to be accounted for by

Important Improvements Made

During the past year, both at mine and mill. Nearly last, but by no means least of these, is the introduction of a rock breaker, the immediate effects of which were a still further reduction of the pay roll, and, which was more im-

portant, an increase of fully twenty per cent in the crushing capacity of the stamps.

The ore treated during the last six months, at least, was peculiar in this respect, that by far the greater part of its value consisted in native silver dispersed through quartz, heavy spar, "altered porphyry," zinc blende, and galena, with a small proportion of pyrites, and some

a notable quantity of heavy gangue matter of at least as great specific gravity as the zinc blende and copper pyrites. The headings were required to be worth \$1,000 per ton by assay.

Under such conditions it would be absurd to expect any machine to yield extremely poor tailings by a single operation. Repeated experiments, by the most careful vanning, demon-

strated the impossibility of obtaining a rich product from the tailings, unless they were previously reground; but they also proved that sixty-five per cent at least of the value of the tailings was contained in from ten to twelve per

cent, confirmed by trials in a pan which would contain about 300 pounds of ore, that the original ore or any of its products, headings, tailings or middlings, could be worked by amalgamation to a higher percentage of its assay value; the ore yielding about seventy-five per cent, headings eighty-seven to ninety-three per cent, middlings seventy-five to eighty per cent, and tailings fifty to sixty.

Under these circumstances it would seem that the better way in which to treat the ore would be to concentrate so as to put ten or less tons into one, and amalgamate the product; or, to concentrate the rich portion as was done for exportation, and reconcentrate, on a cheaper and more capacious machine, producing an inferior grade of material for amalgamation.

The results.—In the latter way a net profit of from \$3,000 to \$5,000 or more per month would be made, an advantage which one would suppose even a rich company could not afford to overlook; but although these facts and suggestions were laid before the management some months since, the only apparent result, excepting the two ripple sluices, has been that the company had no further use for the metallurgist who gave them the information, and who was kindly permitted to resign without explanation or cause assigned. This incident will probably stimulate the ambition of some other metallurgist who desires to advance the interest of his employers while gaining some credit himself, to undertake uncalculated labors, discover an important fact and—keep it dark.

C. H. AARON.
Pinal, Ar., April 15, 1883.

ASTONISHED MINERS.—Down in the Flowery district, day before yesterday, says the Virginia Enterprise, some miners, who were prospecting about two miles north of the Lady Bryan mine, had quite an astonishing experience. They were drilling a hole into a quartz vein on the side of a mountain, preparatory to put in a blast. One of the men was holding and turning the drill while the other was striking. Suddenly a blow of the hammer sent the drill out of sight. Instantly a stream of water spouted up to the height of forty or fifty feet. The water came out the full size of the drill hole, and spouted for over an hour, when it gradually failed and ceased to flow. The men finally put in a blast, and blowing off the top of the quartz vein, discovered some four feet below the surface, a large crevice or cavity, which extended up the hill as far as they were able to probe it.

"GO OUT AND DIG."—A Wood River judge, in response to a man who claimed that, while willing to work, he was unable to find any work to do, replied: "You are a good miner and can therefore prospect. Go out in the hills and dig! The chances are that before your grub gives out, if you work assiduously, you will strike a good prospect that will keep you supplied with money until you can open and sell your claim!"

A COUPLE of eagles that had made their nest on a cliff of basalt, to the west of Mount Davidson, in the early days, disappeared in 1865. A few days ago they returned and commenced the work of repairing their old nest. The miners hail their advent as a good omen—luck for the Comstock.

Fig. 4.—ENGINE HOUSE CLAMPING JAWS

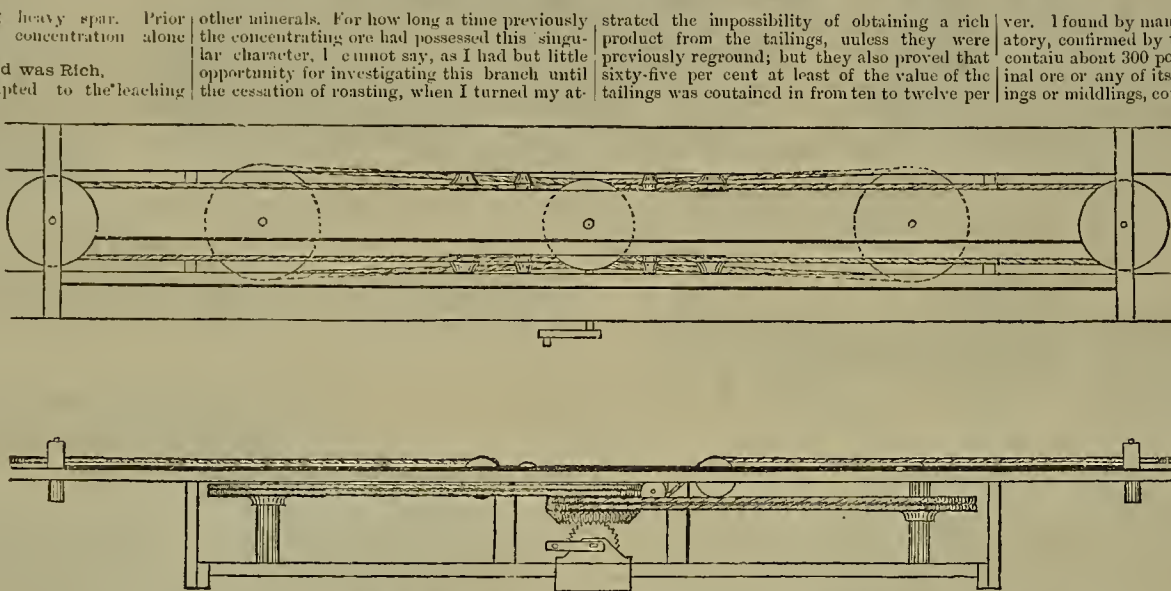

Fig. 5.—PROPULSION POWER, ALSO A REGULATOR FOR GIVING A FASTER OR SLOWER SPEED OF TRAVEL ON DIFFERENT POINTS OF THE ROAD.

teution to it with the object of improving the Work of Concentrators.

The concentrators saved from eighty to eighty-four per cent of the value of the ore. It was from no fault of the machines or their man-

agement that a better result was not secured, but was due to the onerous conditions under which they worked. The ore, as stated above, was charged with native silver. It was crushed somewhat coarsely through a number two needle-punctured screen—a little coarser than a thirty-mesh wire sieve, I believe. It contained

cent of their weight, in the form, chiefly, of native silver enclosed by particles of zincblende, copper pyrites and heavy gangue. This material (middlings) assayed from \$30 to \$50 per ton. The tailings also contained a very small

Figs 1 and 2.—TOP AND SIDE VIEW OF ENGINE HOUSE.

quantity of fine black sulphurets assaying about \$140 per ton when cleaned. The only attempt yet made to save this valuable material was to put in two lengths of wave-line riffle sluices, partly zinc-lined, partly blauketed. This was not done under the writer's direction, and was but a poor attempt. The wave-line riffles were

not so good as plain riffles for the heavy sand containing native silver, while the blankets, which would catch the fine sulphurets in a plain sluice, could only do so in these at higher points, the depressions being quickly filled by the heavy sand, over which the fine sulphurets glided, not sinking through them. Of course, two lengths of sluices were quite insufficient for the work of saving some six or eight tons of stuff per day, and they required the labor of two men, shift about. The work could be better and more cheaply done by automatic machinery. With the crude appliance described from one to one and a half tons of middlings were saved daily, while four times that quantity went, and still goes into the creek, where are some thousands of tons of tailings which the company will not save and will not sell, and which the first summer freshet will sweep to utter loss. As a result of the fact that the value of the ore was chiefly native sil-

Arizona in General.

Said Baron Alexander von Humboldt, "The wealth of the new world will be found in Arizona and New Mexico." Arizona, "the land of the beautiful zone," or "the land of the beautiful maiden," has hitherto been almost inaccessible. But the Atchison, Topeka and Santa Fe railroad has now opened the door of this wonderful territory to the civilization and capital of the east. The Territory of Arizona is bounded on the south by the Republic of Mexico, on the east by New Mexico, on the north by Utah, on the west by California. Colorado touches it at the extreme northeastern corner, and Nevada impinges upon its northwestern boundary. Speaking with exactitude, Arizona extends from 109° to 114° 25' west longitude, and from 31° 37' to 37° north latitude, which corresponds to a width and breadth of nearly 325 miles each, and an area of 113,916 square miles, or of 72,906,240 acres. New York, Pennsylvania, New Jersey, Maryland and Delaware could be set down inside this square without crowding each other. Until 1863 this vast area was a part of New Mexico, but in February of that year was made a separate political division. Arizona is essentially mountainous, and a list of the ranges chopping it up like the ocean waves under a cross wind would be a very long one. The general "dip" of the land is to the southwest. In the northern and eastern parts the plateaux are nearly 6,000 feet high, while to the south and west they are but a few feet above the level of the sea. This grand slope is one

Vast Network of Mountains.

Starting at the southeast corner and going west, south of the Gila river, the principal ranges are as follows: Peria, Pedrogoso, San Jose, Hauchuca, Dragoon, Chiricahua, Peloncillo, Pinalena, Galiuro, Santa Catarina, Tortililla, Tucson, Santa Rita, Atascoos, Cababi, Quigotoa, Santa Estrella, Sierra de la Nari, Sierra del Ojo, and Mohawk range. Between the Gila river, which crosses the Territory from east to west across its southern third, and the Atlantic and Pacific railroad, which bears westward midway between the Gila and the northern boundary line, are to be found the Big Horn, Eagle Trail, Plumas, Mt. Hope, Juniper, Black Hills, Verde, Mazatzal, Magallon, White, Apache, Gila, Salt River and Bradshaw mountains. The northern third contains the Virgin Range, Hurricane Ledge, Shearwitz Mountains, Buckskin Mountains, Calabasa Mountains, Rabbit Hills, and the Vermilion cliffs. The drainage of this network of mountains is almost perfect. The course of the Gila has been alluded to. Besides this river, which is over 500 miles long, there is the famous Colorado which, as the San Juan flows westward from Colorado, unites with the Little Colorado at White Bluffs, and thence as the Colorado flows southwest and then south, forming the Nevada and California boundary lines, and receiving in its course the Pahria, Virgin, Williams Fork and Gila rivers. The San Pedro, San Carlos and Verde are the principal tributaries of the Gila. That Arizona is well wooded the following names would seem to signify: Navajo Forest, Black Forest, Colorado Forest, Cocoonio Forest, and so on to the end of the chapter. Open plains are found in the southwestern and southeastern sections. Though

The Climate of Arizona

Is essentially a warm one, yet the air is dry, pure and remarkably salubrious throughout the greater portion of the year. It is what might be called semi-tropical in the southern portion, where for two or three months of the year the heat is somewhat excessive, though cases of sunstroke are unknown. The winters are delightful beyond imagination by northern people. "In winter," says J. Ross Browne, "the climate near Yuma is finer than that of Italy. It would scarcely be possible to suggest an improvement." In the mountains of Western Arizona, for the greater part of the season the higher peaks are white with snow, rendering the pure, dry air deliciously cool and enjoyable, especially at night, when a good supply of covering is always in demand for the sleeper. Within a distance of 200 miles from north to south a greater variety of climate can be enjoyed than between Maine and Florida on the Atlantic coast. The climate of southern Arizona is superior to that of Florida, in that it is warm and at the same time dry. As soon as this great sanitarium is fully known it will become for winter what Colorado now is in summer—a great resort for invalids. From the middle of June to October, however, the heat is intense, but travelers say that, even with the thermometer at 120 degrees, sunstrokes are of rare occurrence. This is due to the rarity of the atmosphere. The average rainfall at Fort Mojave is but little over five inches, distributed through August, December, February and June. At Camp Grant, which is said to be in all respects a medium climate, the diurnal variations of temperature are from fifteen to thirty degrees; the monthly range being about twenty-seven degrees, and the yearly extremes of heat and cold thirty-four and ninety-six degrees, respectively. There are, annually, about sixty-five days of rain and hail, and three of snow. At Camp Verde the temperature ranges from five degrees to 113 degrees, and the average rainfall eight inches. At Camp Lowell, seven miles east of Tucson, the diurnal range is sometimes seventy degrees. Persons afflicted with pulmonary complaints experience speedy relief in this warm atmosphere, and many won-

derful and well-authenticated cures of this nature are reported.

The Scenery is Truly Charming.

It is not so rugged, perhaps, as Colorado, but it is, if possible, more pleasing. Instead of having a continuous mountain chain running in a given direction, it has isolated peaks and detached sections coming up out of the plain apparently at random. Yet, while her landscapes are thus beautiful to a degree that admits of no rivalry, Arizona has her towering peaks and deep canyons surpassing those of any other locality. The canyons on the Colorado river are some of them 6,000 feet, or more than a mile, in depth. Mention should be made of the valleys of Arizona. They are numerous and fertile. In the valley of the Verde, settlements have been made to a considerable extent. Williamson's valley, near Prescott, contains not less than 500,000 acres, together with 300,000 acres of adjacent foothills, well furnished with bunch grass. Around Mount Hope, in Yavapai county, there are scores of beautiful valleys containing from 40 to 400 acres of land each, in fact, wherever a river runs, there, at some portion of its course, may be found as lovely depressions as exist anywhere in the United States. It is estimated that there are about 2,800,000 acres of land in the Territory, of the very best quality, with sufficient surface water near at hand to properly irrigate. At least 10,000,000 acres more, it is said, can be reclaimed by the use of artesian wells. As compared with Mojave county, in Arizona, the eastern portion of southern California and southern Nevada, in the same latitude, have the following relative standing: Agricultural, irrigable and arable, California and Nevada, two per cent.; Arizona, twenty-five per cent. Timber, California and Nevada, six per cent.; Arizona, ten per cent. Grazing, California and Nevada, eighty-eight per cent.; Arizona, thirty per cent. Baren, California and Nevada, four per cent.; Arizona, thirty-five per cent.

The following agricultural divisions of Arizona are of interest: 1. The Colorado river country. 2. The valleys of the Gila and tributaries. 3. The Santa Cruz valley, and certain parts of Pinal and Pima counties. 4. The Colorado-Chiquito. 5. The country around Prescott. 6. Mojave county.

As far as known Arizona is abundantly supplied with hot springs. They have been noticed in the Grand Canyon of the Colorado, also on the Gila and Prieto rivers, on the Mesa near Camp Lowell and near Tubac. The Monroe Hot Springs, on Castle creek, sixty miles south of Prescott, are most widely known. The temperature of the water at the springs is 160 degrees, but two yards below it cools to 130 degrees.

In Population and Wealth

Arizona is rapidly advancing. According to the census of 1876 the population consisted of 30,191 whites, besides 25,000 Indians. Since that time the increase has been rapid, and the census, if taken to-day, would probably foot up nearly 50,000. What were considered the wild dreams of Cremony, in his "Life Among the Apaches," published a dozen or so years ago, are now being realized; and the almost miraculous opening of the country, and the continuous discoveries of rich mineral deposits, lead to the belief that the next ten years will see an inflow of immigrants as yet unparalleled in its wonderful history.

The Principal Arizona Towns

Are Yuma, Ehrenberg, Prescott, Florence, Tombstone, Benson, Tucson, Wickenburg, Phoenix and Globe. Yuma is located near the junction of the Gila and Colorado rivers, and is 466 miles from Deming, N. M., on the Southern Pacific railroad. It was founded as a mission in 1700 by Father Kino. The population is now probably over 2,500. Ehrenberg is 130 miles above Yuma, on the Colorado river, and is a town of nearly 1,000 inhabitants. Prescott, established in 1864, and county seat of Yavapai county is a handsome, homelike city, situated in a small valley, surrounded by mountains, and boasting of a population exceeding 4,000. The capital of the Territory, first located at Prescott, was taken in 1867 to Tucson, but in 1877 was taken back to its first love. Phoenix, the county seat of Maricopa county, is situated two miles north of the Salt river, and is the business centre of a highly productive valley. It was founded in 1868, and contains 800 inhabitants, half of whom are Mexicans. Wickenburg, a village of 300 people is a mining town, situated at the forks of the stage road to Prescott from Ehrenberg. Florence, the county seat of Pinal county, lies on the Gila river, 225 miles from its mouth. It is the centre of the rich agricultural valley of the Gila, and contains about 1,800 people, evenly distributed between Americans, Mexicans and Spaniards. Globe is a recent vigorous outgrowth of mineral discoveries in the mineral district of that name, ninety miles northeast of Florence, on the Pinal Creek. The early origin of Tucson cannot be easily traced, but it is thought to have been founded but a few years after Santa Fe, in 1580. Up to 1800 it was a mere presidio, or garrison, with a population of a thousand souls. In 1856 it is described as containing only 400 inhabitants, while to-day it supports nearly 5,000 people. The future importance of Tucson is easily predicted. Tombstone is a recent "outpost." It was founded and named by a miner who made a wonderful strike contrary to the gloomy predictions of friends, who asserted that he would find his tombstone in the district to which he was going. It is the county seat of Cochise county, and is

situated twenty-seven miles southeast of Benson, on the joint line of the A. T. & S. F. and Southern Pacific railroads, being easily reached from Benson by a daily line of Concord stages. The buildings of the town are of a superior order, and church and school privileges exist in abundance. The present population is estimated at 4,000. Benson is an important station on the roads mentioned, and will increase in commercial importance with the opening of the road from that point south to Guaymas.—From River to Sea.

Early History of Mohave County.

Maynard District.

The Mohave County Miner gives an interesting sketch of the early history of the county:

In the early part of the year 1863, John Moss, William Furlong, Wm. France and two other men named Walton and McCall, prospected through the Union Pass range, which lies on the east side of the Colorado river. At that time the only settlement in Mohave county was at Hardyville on the river, some nine miles above where Fort Mohave now stands. The result of this trip was the location of the celebrated Moss mine by John Moss, one of the party. This is a gold ledge about fifty feet wide and averages about 814 across the entire ledge, and was the first location made in Mohave county. The wonderfully rich specimens of gold taken from this mine created a great excitement in San Francisco and resulted in the sale of the mine for \$90,000.

Of this first prospecting party none are alive at the present time. Billy France was lost a year or two after in the mountains between Mineral Park and Cedar and perished. McCall was killed by the Indians at Union Pass in 1866. John Moss died in California a year or two ago.

The discovery and sale of the Moss mine resulted in the formation of another prospecting party by San Francisco mining men, who sent out a party of ten or twelve under the guidance of John Moss, among whom were Howard B. Coit, for many years since the caller of the San Francisco stock exchange, and Lieut. Evans of the California volunteers. This party prospected through the Union Pass, Cerbat and Wallapai ranges of mountains in the fall of 1864 and finally located on the western slope of the Wallapai mountains, where they formed a district under the name of the Wanba-Yuma district, which included in its boundaries the entire Wallapai range, of which Maynard district, the subject of this article, now forms a part. The party made several locations, but were driven out by the Indians after working two or three months.

In the year 1866 the same party came back again and worked about three or four months on two of their locations, the Pride of the Pines and the Florence, which are some six miles north of the copper mines now owned by H. A. Owens, J. A. Smith, John K. McKenzie and others, when they were again compelled to leave the district by the Indians, who made Mohave County from this time up to the year 1870 too hot for white men to live in except at the settlement at Hardyville on the river. From this time little or no mining was done in the county until the year 1870, when several small parties ventured into the mining country again and formed settlements at Mineral Park, Cerbat and Chloride. In this year Lieut. Wheeler first visited this county and surveyed the site of the present Fort Mohave and the Indian reservation.

Having been detailed by the U. S. Governor to examine portions of Nevada, Utah and northern Arizona for the purpose of reporting on the geological and mineral formation of the country, Lieut. Wheeler again visited this county in the fall of 1871, and camped for several days in the main wash running into the valley from the Wallapai mountains, which has since been called Wheeler's wash. With this expedition, which came from Nevada by way of Death Valley and El Dorado canyon, came also Major Wheeler, a brother of the Lieutenant, and a party of prospectors, who were outfitted by San Francisco capitalists, among whom were F. L. A. Pioche, Isaac Friedlander, A. J. Bowie, F. R. Simonson, Frank Soule, and others whose names appear on the older locations made by this party. Major Wheeler and his party at once proceeded to business on their arrival in Wheeler's wash, by building a house and forming a permanent camp, which they christened "Bottle Camp," from the number of medicine bottles they had with them, we presume. They at once formed a new district, under the name of Maynard district, adopted a set of by-laws and regulations, and elected Francis Klett as Recorder. Among those who were present in the district at its formation, the following are the best known, viz.: E. Martin Smith, Francis Klett, Lafayette Maynard, from which the district was named, John Kohler, W. McGeary and D. W. Lockwood.

The first location made by the party was named the Wheeler ledge, and there are some 10 names signed to the notice of location. The boundaries of Maynard district are as follows: Beginning at a point distant 10 miles due north from the Lyons ledge; thence due east seven miles; thence due south 20 miles; thence due west 14 miles; thence due north 20 miles; thence to the place of beginning.

The general formation of Maynard district is in granite mostly, in some places feldspathic granite; the ledges large and well defined, varying in width from two to 20 and 30 feet, the ore streak measuring from six inches to six feet. The ore is generally chloride and carbonate on

the surface, changing at a depth of 50 or 60 feet to sulphuret. Considerable galena ore is found in this district, notably in the Antelope mine, which will be described hereafter. The ores of this district are rich in ruby and antimonial silver, and vary from 50 ounces to 1,500 ounces. There is a streak of ruby-silver ore in the American Flag mine about four inches in width, which will average over 1,000 ounces to the ton. Considerable work has been done on some of the mines of this district, at a vast expense, which goes to show that the mines are rich, for this work has been done during the past 10 years, when nothing less than \$150 ore would pay to mill in this county.

The most prominent mine in this district is the American Flag, owned by Messrs. Richards, Corin & Co. There has been more work done on this mine than in any other in this portion of Mohave county, and the mine is opened up in better shape and has not been gutted out like a great many of our mines here. Everything has been done with a view to the future working of the mine and not with a view of getting out everything in sight and leaving it. On this mine, which was located in October, 1874, the main shaft is 250 feet deep, and there are two tunnels, one 691 feet long, tapping the shaft at 250 feet, and another 603 feet long. Up to the present time there have been about 3500 feet of drifts, tunnels, winzes, etc., run in this mine, which has produced about \$130,000. The ore from this mine is a sulphuret, carrying pyrites of iron, some zinc blend and a slight percentage of lead, the silver being antimonial and ruby. This is one of the most promising mines in Mohave county and great results are expected from it in the near future.

Another good mine in this district is the Mississippi, owned by Frank Hamilton, with a tunnel about 420 feet long and a shaft 250 feet deep, at the bottom of which the pay streak is fully three feet wide and will average over \$50 per ton. Thirty tons of the best ore from this mine milled \$900 per ton at the Mineral Park mill.

Another prominent mine is the Antelope, owned by B. H. Spear and Wm. Freeborn. This mine is opened up by about 400 feet of tunneling and a shaft 100 feet deep. The ledge is five feet wide of carbonate ore on the surface carrying a good percentage of lead. Below the water level the ore changes to a heavy sulphuret. Ore from this ledge will assay from \$25 upwards. Considerable of the best ore has been hauled to the mill at Mineral Park and all of it went over \$300 to the ton.

Still another prominent mine and one of the first locations in this district is the Dean mine, with a strong, well-defined ledge twenty feet in width, with hard blue granite walls on either side. On this ledge there is a shaft 140 feet deep with five feet of ore at the bottom which will average fully \$80 per ton. There is also a tunnel 600 feet long which enters the ledge at a depth of 400 feet, showing similar ore, in extent and value, to that found at the bottom of the shaft. This valuable property is now owned by John E. Ryan, who has no superior as a miner in this county, and who has spent a large amount of time, money and muscle in getting this mine into its present shape.

Other valuable properties in this district are the Southern View, owned by Gatewood & Co.; the Grant & McGeary mine, owned by Tubman Ayres; a group of mines, owned by Harley Fay and T. L. Ayres, and some good claims owned by John Barry.

These are only a very small portion of the

Ledges Found in this District.

And a great many others have been located by various other parties which, with a little work, will develop into as good mines as those referred to above. This district contains an abundance of wood and water, and a large portion of it is covered with heavy pine timber from which most of the lumber used in building and mining in this county for the past ten years has been cut. The district includes in its boundaries the highest peaks of the Wallapai range, rising 9,000 feet above the sea level. The high altitude of the district makes the climate perfectly delightful, healthy and invigorating, and though the miner may find more snow than he wants in winter the cool summer days will more than compensate him. Mining timbers of any size can be procured at the sawmill near the Dean mine at very reasonable rates.

To the prospector in search of new fields to display his enterprise and energy Maynard district presents attractions not equalled by any in the Territory of Arizona. Containing as it does a large tract of mineral land which has as yet been scarcely prospected, the great size of its ledges, the high grade of its ores and the facility with which they can be worked, taking all this into consideration, together with the fact that the Atlantic and Pacific railroad now actually passes within twelve or fifteen miles of the mines, it will be readily seen that this district offers advantages to prospectors not excelled anywhere. We confidently expect that the day is not far distant when hundreds of men will be found at work on the American Flag and Dean mines alone, and that each of these mines will support a twenty stamp mill of its own, as every one familiar with them will acknowledge they are abundantly able to do. To prospectors and strangers from afar in search of good mines and something that will pay to stay with and develop, we say take a look at Maynard district.

Pure, weak and sickly children need Brown's Iron Bitters. It will strengthen and invigorate them.

Improved Form of HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above cut of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "bucking," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro Glycerine Powder, as safe to use and handle as any other Nitro Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

A Cheerful Recommendation.

BENICIA, CAL., February 4 1883.

Messrs. Dewey & Co., Patent Solicitors:—I am in receipt of my patent, "Improvements in Vehicle Brakes," obtained through your Agency, and would say I am much pleased with thorough and graphic description in specifications and drawings, and can cheerfully recommend you to anyone wishing to obtain favors in your line.—Truly yours, G. R. DUVAL.

Cash in Advance.

Our terms are cash in advance for this paper. NEW NAMES will not be entered on our printed list until payment is made. Feb. 1, 1884.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

BYRON JACKSON,

Manufacturer of

Agricultural Machinery, Engines, etc.

625 to 631 SIXTH STREET, SAN FRANCISCO.

Close regulation,
and best attain-
able Economy
of Fuel.

Designed for
heavy and
continuous
work, and
adapted to
any required
speed.

The above cut represents my **NEW AUTOMATIC, PERFECT-REGULATING, VARIABLE CUT-OFF STATIONARY ENGINE.** I claim that this Engine is fully up to the advanced modern practice, both in Engine and Steam economy. I have given particular attention to the weight of the Fly Wheel to a given power, as well as proper speed to secure the greatest economy in fuel and wear and tear of Engine. I claim that these Engines are **First-Class**, both in design and make, and fully equal to the latest Eastern styles.

I will manufacture my Engines to order of any size and speed up to 200-horse power. I recommend a moderate high speed, but will please my customers in that respect. I wish it understood that I believe in high-speed Engines, and will guarantee my Engines, fitted with Jackson's Automatic Cut-off Governor, to furnish a given power at 20 per cent. less, first cost, than a Corliss or Rider Cut-off, and less costs for repairs and running expenses, with equal economy in fuel for each horse-power. I will also manufacture to order Portable and Traction Engines, fitted with my Jackson Automatic Cut-off Governor, and guarantee satisfaction.

I Manufacture

SELF-FEEDERS FOR THRESHING MACHINES, HIGH AND LOW DERRICKS,

Forks, Blocks, Harrows,

Windmills, Hay Carriers, etc.

BYRON JACKSON,

625 to 631 Sixth Street, San Francisco.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinkley & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringement responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street,

Nov. 6 1882

SAN FRANCISCO, CAL.

PRINTERS, AUTHORS, INVENTORS, PATENTEES, BUILDERS, MANUFACTURERS, MECHANISTS, MERCHANTS, and other trades-people can have satisfactory Engravings and Electrotypes made at moderate prices by the S. F. ENGRAVING CO., No. 405 KEARNEY ST. Send photographs, sketches, drawings, models or samples for estimates. Map and Woodcut Engravings enlarged or reduced by the aid of photography, at less than one-half the cost of the originals and in a short time. Photo-relief, Zincograph and other improved methods employed.

California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING and SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 252 Market St. q. c. Elevator 10th Floor 64.

NOTICE OF REMOVAL.

The Clayton Steam Pump and Air Compressor Works would respectfully announce that they will remove May 1st, to their new works, 45 and 47 York St., Brooklyn, N. Y. (near the approach to the New York and Brooklyn Bridge.)

Notes from Eureka, Nevada.

(CONTINUED FROM PAGE 288.)

chamber through broken ground, which may lead to large ore bodies above that level. In the same chamber, on the June level, are four men taking out ore on tribute.

The November drift is being continued by miners on contract. There are good-looking places in this drift, which if crosscut, may lead to ore. A drift is being run on the main fissure, westward from the Uncle Sam shaft which, it is believed, will lead to ore. This fissure is the same one on which all the large ore bodies in the Richmond mine made, and there is no reason why another body of ore should not be found in this direction. The No. 5, fine dust chamber, is being turned to good account; a track has been laid in it, and it is to be driven further into the hill easterly, for the purpose of prospecting the Allion ground above this level. This is a very good move, and it may result in the discovery of very good bodies of ore. The ore bodies on this level in the Richmond and Eureka Con. mines have helped to swell the dividends for those companies, and may do the same for the Allion company, notwithstanding the present indebtedness hanging over it.

There are several thousand bushels of charcoal, a large supply of wood, and nearly everything on hand needed to run the mine for several months. The current expenses of running the mine must now be very light.

There are quite a number of miners leasing property on Adams Hill, and a very considerable amount of ore is being sent to the furnaces from that locality; so much in fact as to deserve marked attention.

One of the best properties on Adams Hill is the

Oriental and Belmont Mine.

Sums of money aggregating between \$200,000 and \$300,000 have been realized from the ore taken out of the almost numberless holes that have been sunk in the ground. While visiting this mine, a few days ago, my attention was called to one of them where the rock had been quarried out, and from it a sum of money was realized amounting to \$8,000. The ore was gray carbonate carrying \$78 in silver and \$22 in gold per ton. A similar amount of money was realized from ore taken out of a hole to the northward of the first that is not more than fifteen feet deep. Westward from there are several holes, and a shaft, down 150 feet from the bottom of one of them. The latter has been sunk to follow a seam, but it dips away from the ledge. This is the deepest shaft on the property. From the holes in this locality have been taken various quantities of ore, aggregating in value no less than \$20,000.

Near the south end of the survey for the Oriental and Belmont is the initial point of the original Belmont location, marked by an opening in the ground, sunk on an incline of about 20°, to a depth of about forty feet. Out of this Messrs. Bucl and Bateman, in the early days of Eureka district, took out to the value of about \$30,000, which, with some from the Racine mine, lying northward from it, toward the Richmond mine, was the first lot smelted by those gentlemen in the new furnaces they built for the reduction of ores from the Champion and Buckeye mines. Large quantities of ore were taken out of a vertical shaft adjoining, all of it being very rich in lead. The Oriental claims lie to the northeast of the Belmont; the main shaft is down only 38 ft from the surface, and has yielded considerable ore valued at \$60 per ton in gold and silver; it also carried twenty per cent of lead, had a fine quartz gangue and sufficient iron to make it valuable for the fluxes it contained.

The next point of interest, I said, was the old Midas shaft, which has been sunk to a depth of seventy-five feet, and from it a drift has been driven twenty-five feet through a ledge of low grade ore, some of which, however, was worked to a good profit. About twenty feet north from the Midas shaft, there has lately been scratching done on the surface, and quartz broken for flux. Here was also found ore that worked up to \$160 per ton. Near this point are some of the old Midas workings, a series of pot-holes burrowed close to the surface, out of which tributaries took ore enough to realize the net amount of \$20,000 after the ground had been abandoned by the owners as worked out. The Fairview shaft was situated close to this place. It was formerly owned by the Buttercup Co., and was sunk under the superintendency of Col. G. Collier Robbins, who, it is said, cleaned up \$40,000. Around and about this spot the ground has the appearance of California placer diggings that have been worked down to bedrock and deserted. Here, however, the ground is not worked out. There is still ore in sight.

Among the old locations now embraced in the Oriental and Belmont survey were the Newport, Black Ledges, Blue Wing, Meredith, New York and Louisville, which were owned by parties who strove to develop them, but there were so many conflicting titles to the ground at that time that it took all the money they could raise to buy one and another out. In 1871 George Hearst bonded the Meredith for \$20,000, but finding that other and different parties owned the Blue Wing, and that there was a conflict of title, he abandoned it and gave up the bond.

At various times there were several persons who claimed different portions of the ground and took out ore; others there were who chloided without leave, under the plea that they must make a living, and were permitted to do

so, the owners hoping to get rid of them finally, and in the meantime quiet conflicting titles. This was finally done by consolidation and obtaining a United States patent. The Louisville workings, now mainly filled up, have yielded ore from which selected shipments ran as high as \$300 per ton. A portion of this was successfully worked at the Lemon mill. The masses of quartz on this property are enormous; the bulk of it is low grade, running from fifteen to twenty dollars per ton. This it is thought can be worked by milling process, and in such quantities that large profits may arise therefrom.

As to the high grade ore, there is no question about their profitable treatment, they are just what are wanted at the furnaces for their fluxing qualities. There is not a property in the camp so easy of access as this, and had it not been for the succession of difficulties experienced by the owners, the money realized from the sale of ore taken out of the ground at divers times, would have been ample to develop it, and place it upon a dividend paying basis.

In the Pinto District

There is very little doing that is new. The Resene mine is to be started immediately. The tunnel of the Berryman Tunnel and Mining Company is in thirty-three feet in mineralized quartzite. Large quantities of quartz running heavy with lead, are being extracted from the Diagonal mines. The miners of the district will hold a meeting to-morrow for the election of a new mining Recorder, and amending the rules of the district.

J. N. H. JOSEPH.

Tombstone Notes.

[From Our Traveling Correspondent.]

EDITORS PRESS:—The Blue Jacket mine, about two miles westward, report a large body of high-grade free milling ore lately struck. The Gilded Age, right in the city, is being worked by C. J. Barber, who is now rejoicing in a streak of fine free-milling ore of high grade. His is a very cheap and practical hoisting works. The coiling drum with safe ratchet and brake band is driven by a W. I. Tustin, S. F., horse power, to which a span of small mules are attached, and, when necessary, another span can be added. Mr. Barber speaks in highest terms of this horse power. Over the shaft is a tripod for an elevated shieve, under which the bucket passes down the shaft, and the other end of the rope passes to the drum, which is located near the shaft and governed by a brake bar.

Mr. Barker professes to believe somewhat in the divining rod for discovering the exact location of gold, silver or copper, and which of them—and just how far off they are located—and claims in this lead to have been specially instructed by it, and by his work here that he has demonstrated just what the instrument did indicate would be found.

The local papers do not fully commit themselves on the rod question, but they do persistently rejoice when by any means any one is induced to dig where the pay ore is to be found, and do actually find it, and in finding it furnish good honest labor for the willing working miner.

Tombstone is favored with two daily papers, the *Republican*, revived from the ashes of the *Nugget*, and the sober, solid *Tombstone* inscription called the *Epitaph*. This journal sometimes forgets the solemnity of its surname and perpetuates huge jokes with its *Republican* neighbor. Each office makes us a very readable daily and weekly issue for country circulation.

Foundry and Machine Works.

McAlister & McCone of Virginia, Nev., have established a large foundry with iron lathes, planers and various heavy machines to build and repair mills and mining machinery. Mr. McAlister takes charge of this branch of their business. Their pattern rooms show somewhat the proportions of their operations in heavy machinery castings.

Tombstone Blue Stone and Acid Works.

Mr. C. J. Duval, assayer and mining engineer, has quite extensive acid and blue stone manufacturing works and is prepared for and filling orders from various parts of the Territory, thus saving long delay and high expense of railroad transportation from San Francisco.

This is considered a valuable and essential enterprise for the mining interest of the Territory. An order for six barrels of blue stone came in from the Total Wreck mill the other day. He manufactures the sulphuric acid to sell by the carboy and also for use in manufacturing the sulphate of copper—blue stone—from the rich copper ores produced here. I have not space to describe the many interesting processes of this busy establishment.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves.

Subscription rate, \$4 a year.
N. B.—Personal attention will be called to this (as well as other notices, at times) by turning down a leaf.

Copper.

Its Uses, Product, Value and Method of Working.

Copper was one of the first metals known to man. In an age so remote as that in which Adam and his immediate descendants were the only human inhabitants of earth, mines of copper were worked and their products fashioned into tools and utensils, but were far more extensively used for the manufacture of ornaments for the persons and the homes of the early inhabitants of our world.

Tubal Cain in the seventh generation from Adam—was an adept artificer in copper and brass. Chops worked successfully a copper mine on the Peninsula of Sinai. The ancient Egyptians, who possessed the art of hardening copper—combining with it an alloy of tin—made their tools of this metal, and employed them in the working of stone, and other metals. The first coins used by man were made of pure copper. It was consumed in large quantities by the Syrians, Phoenicians, Greeks and Romans in the construction of monuments and statues.

That the ore was

Worked Extensively by the Ancients,

Is evident from the various implements, utensils, ornaments, etc., which have been discovered beneath the ruins of buried cities in Egypt, in the tumuli in Denmark, in the quarries of the Aztecs at Mitla, Mexico, and in the copper mines of the United States, some of which were unquestionably worked by a race of people who preceded the Indian in the occupancy of North America.

Some idea may be gathered as to the extent to which the industry was prosecuted, and the facilities enjoyed for working and fashioning the products of the earlier copper mines of the world, from the following extract: "The Colossus of Rhodes, after having lain in fragments for centuries, is said to have required 900 camels to convey its pieces away."

In the middle ages, however, the production and use of copper would seem to have been in great measure abandoned, probably because of the discovery of the more precious metals with which it was found associated. At least the records of that period in the world's history contain little concerning the working or use of the metal.

In the Tenth Century

A copper mine was worked near Goslar, in Lower Saxony. In the twelfth century the Fahlun mine, in Sweden, was worked, and in the thirteenth century, the mines of Thuringia were extensively developed. From that time until the latter part of the eighteenth century, the copper mines of England yielded this metal more extensively than those of all the rest of Europe combined. So late as 1854, a noted writer said: "Great Britain exceeds all other countries in the number of copper mines and the value of their products."

In the year 1844,

The Lake Superior Copper Mines

Were discovered, and these have since proved to be the richest and most productive mines of this metal in the world. Abundant evidences of the previous working of these mines were found in the rude stone tools and the primitive appliances for reducing the ore which had been left by an unknown people, who had, in ages past, inhabited this continent, and whose history is unwritten.

These pre-historic workings were sometimes twenty feet in depth. Upon the rubbish that had partly filled the pits large trees had grown. A hemlock growing above one of these excavations was found to have over 350 annual rings of growth. Masses of copper over six tons in weight were found, that had been worked free from the vein, and cleared by fire from the vein-stone that had filled their interstices. Ashes and charred wood were found about them; evidence that an effort had been made to reduce their weight to a proper volume for transportation and further reduction.

In one of these mines a mass of virgin copper, forty-five feet in length by over eight feet in thickness, was found, the estimated weight of which was five hundred tons—yielding ninety per cent of pure metal. This was found in the Minnesota mine, in the Ontonagon district, Michigan.

Since the discovery of the Lake Superior deposits, the copper mines of the United States have, until recently, yielded a sufficient supply to meet the demands for home consumption, leaving, also, a large surplus for export.

The Total Yield of Copper

Of all known mines in the world, from 1830 to 1853, is given, approximately, as follows: In 1830, 25,500 tons, of which the mines of the United States gave 50 tons; in 1840, 41,000 tons—U. S., 100 tons; in 1850, 54,700 tons—U. S., 650 tons; in 1853, 55,700 tons—U. S., 2,000 tons.

From these figures it will be seen that there was a rapid advancement in the production of our copper mines up to the last date above mentioned. Ten years later, the aggregate yield of these mines in America was equal to that of all the other copper mines of the world.

The Usefulness of Copper.

Next to iron, copper is the most useful metal. In its general distribution, it comes next to that most important of all metals. The qualities of durability, malleability, ductility, etc., it possesses, render it well adapted for a great variety of purposes. Its disposition, moreover, to form alloys with other metals—for which it is particularly remarkable—causes it to be largely

used for the production of numerous compounds; and thus it is made to perform the service of a great number of different metals possessing a variety of qualities.

In this connection we should not omit to mention the fact that the immense consumption of copper for electrical purposes,—which with a single company in the east (Edison's) reaches twenty tons per diem—will afford a vast stimulus to this industry during the current year. No fear need be entertained that the steadily increasing supply from mines on the Pacific coast will cause the supply to be in excess of the demand for home consumption.

Yield and Value in 1882.

The entire product of all the mines of this metal, during the year ending December 31, 1882, at a moderate estimate, was not less than 100,000 tons of ingot copper, in the United States alone. Estimating this at eighteen cents per pound, we have a total value of \$36,000,000 for the year.

During the month of February last, seven Michigan mines produced 2,124½ tons of ingot copper,—124½ tons more than the total yield of all mines in America during the year 1853.

The Price of Copper

Fluctuates according to the demand and supply. At the beginning of the present century, owing to exhaustion of mines in England, resulting in great scarcity of the metal, the price advanced to £128 (\$640) per ton.

During the past few years market rates have varied from 15 to 20 cents per pound. New York quotations show rates in February last at 16½¢@16½¢ for Baltimore, 16½¢ for Arizona, and 17½¢@17½¢ per pound for Lake.

The various uses to which copper is now applied are so enlarged that the price is likely to be steadily maintained, notwithstanding the rapidly increasing production. It is the prevailing opinion among those best informed on the subject, that no material reduction in prices may be looked for for several years to come.

Profits of Copper Mining.

Probably no field of mining venture affords such inducements for investments as copper mining. The Calumet & Hecla mine, it is well known, has paid some \$22,000,000 in dividends to its shareholders, while most of the other Michigan companies have paid from thirty to fifty per cent per annum on their investment. During the past two years most of the copper mines operated in Arizona and New Mexico, notably the Copper Queen, Old Globe, Loug-fellow, Detroit, Omega, etc., have made large returns to the owners. It is evident that the business is sufficiently safe and profitable to offer great encouragement as to the future of this industry in our own country.

The Reduction of Copper Ores.

In the reduction of copper ores various systems have from time to time been adopted, the method being subjected in part to the character of ore worked and general existing conditions. For many years the business of smelting copper ores was carried on almost exclusively at Swansea, South Wales, near the mines of Cornwall and Devon, ores being shipped to that point from all parts of the world. Until the past decade, but little was known of the great resources of the Pacific States and Territories in copper. Some developments had been made in various parts of the country of a most promising nature, and much money spent in reduction works, based upon former methods of working, but the attempt to introduce the systems and practice of the Old World into the new, in this, as in many other things, was attended with disastrous failure. The new conditions were not suited to the old order of things. In this emergency Messrs. Rankin, Brayton & Co., of the Pacific Iron Works, in this city, a firm representing the most advanced ideas of modern practice in everything relating to the mechanical appliances for treating ores, conceived the idea of applying the principle of the water jacket furnace to the reduction of ores, and instituted a series of experiments, with a view of determining what form of jacket was best adapted to the purpose, as well as the mechanical construction necessary to withstand the severe ordeal that such work would be subjected to. After some years of persistent and costly experiments, a result was reached which has made

A Revolution in the Method of Copper Reduction

And which has created an industry that has been a source of vast increase in the wealth of the country.

It is no exaggeration to say that the extraordinary development of the copper interest in all our mining States and Territories owes its origin and present progress to the invention and general introduction of the Pacific Copper Smelter. This furnace has revolutionized all former methods, and made practicable the treatment of all classes of copper ores by a single process—so simple in operation and so economical in results that there is scarcely a copper mine anywhere, located favorably as to fuel and transportation, that cannot now be profitably worked.

Every successful copper enterprise in the country, without an exception, we believe, is being operated by this system of reduction. The manufacturers are now receiving orders for their smelters from nearly every mining country in the world, and the system seems likely to soon become universal. The same system of reduction, it may also be said, has been applied, with equal success, to all grades and classes of galena ores.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slog Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 8x10 to 18x30. This latter size furnished J. R. Huggin for Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x30, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trunnels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 30x30. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanics in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to our address,

For Sale by DEWEY & CO., San Francisco.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address, ALMARIN B PAUL,

Room 20, Safe Deposit Building, San Francisco

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 26, 1883.

Mr. A. B. Paul:—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quick-silver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which glides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them. B. O. McLAIR, Superintendent Indian Spring Drift Mine.

Benson.**The Total Wreck.**

(From our Traveling Correspondent.)

The Total Wreck Co. are said to have a very perfect mill for the treatment of free ores equal to any now in the Territory. They have the M. P. Boss pans and process, which keeps a continuous flow from battery to settler. They have cars of five-ton capacity to circle around the hill from mine to mill on tramway. The ore is there dropped in bins above the crusher or breaker, and all planned for labor saving. The twenty-stamp mill has a capacity of sixty-five tons per day. A Corliss engine with fly-wheel of fourteen tons, and eighteen feet diameter. The whole planning contemplates the doubling of the number of stamps at an early day. The mill, under the superintendence of Mr. W. Armstrong, promises success—no, not promising—but producing the regular shipments of bars to New York; the shipment of March 19th was \$20,000. They are reporting ore of assay value \$100 per ton from the 300 foot level, and the ore now in sight is estimated at not less than \$3,000,000. Mill and mine about eight miles from Benson railroad depot, and fifty miles from Tucson, their main business point.

Benson is on the S. P. and Atchison and Topeka railroad, 1,024 miles from San Francisco—elevated 3,578 feet above sea level with a population of 500. It has a thriving American look. It is the junction for the S. P. and Sonora railroad, now running to Guaymas, and the depot for Total Wreck and other mines.

Benson Mining and Smelting Co.

It has the first furnace, now in full running, on smelting ores. The furnace is of the improved jacket—with capacity of thirty tons daily. They have railroad switch, and deliver their ores and freights right at the works. They purchase the ores at assay value after a systematic sampling—allowing twenty dollars for cost of smelting, and small percentage for loss in working. This is eastern capital, and an investment that promises well for the stockholders.

The plan of the company is to add more furnaces as the business will warrant. They were getting ores from Mexico and from their own mines in Lake valley, near Phoenix. Most of their silver ores they were getting from Tombstone mines. Were working Harshaw ore at the time I visited them. They use English and American coke mostly for fuel. They are getting ores of different classes, and purchasing them all, enabling them to use one kind to flux another.

Old Tins and Scraps of Iron Valuable.

They use lime, and large amounts of old sheet iron, old tins, etc., to mix in with the ore as flux—pay there twenty dollars per ton for old scraps and tins. This company will be of great service to the many prospectors.

This is an encouraging feature for Arizona's prospectors. There are now numerous mills and smelters that will give them a fair valuation for their ores, and thus enable them to go on and open up their own ledges by their ore yield.

Benson was a very lively place till the Mexican railroad and depot buildings were completed, but now has not so large a hotel patronage. As the pay ore discoveries increase in the neighboring hills, will Benson grow and prosper. It is the prospector that invites the distant capitalist to come and invest. I often think the prospector is underrated in his self-sacrificing and risky adventures.

I met in Benson, Mr. Durfee, an early pioneer of Reese river and Nye county. One of the best of our lone prospectors—Mr. Durfee—sold a mine in Cornucopia, Nevada, about seven years since for \$12,000, then made a visit to his friends east and there took the Black Hills mining fever, and visited those diggings, but was not satisfied with the place; and, coming in contact with one who had been in the African gold mines, Mr. Durfee caught the African gold fever and started for that country, but first toured a while in Europe, then sailed from England for Africa, but found the mines very largely monopolized by English and Australian capitalists and very little encouragement

for a poor man. So he directed his course back, to rejoice over his rights as an American citizen, and to live in a better mining country than he found in all his travels. He now has some locations made in this vicinity that may yet prove equal to Total Wreck.

I daily see those who have their good sample ores of ledges yet to be developed by those who have cash, but not the courage and muscle to pack their camping requirements and spend years in search of this paying mineral. There is a disposition to speak too lightly of the small prospect shaft sunk by the discoverer of the lead. He may be, has sunk forty-nine holes and paid cash for many assays, before he found this one that he invites capital to invest in, for a small fraction of its supposed value. He is the one who braves the dangers of the murderous bands of roving Indians. Almost daily do our local papers here announce the slaughter of prospectors by Indians. W. B. CROWELL.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PULLEY BLOCK.—Byron Jackson, of S. F., and Geo. W. T. Carter, of Byron, Contra Costa Co., Cal. No. 275,916. Dated April 24, 1883. The improvement in pulley blocks consists of a skeleton two-part iron shell, which is bolted together at the top and bottom, and has chambers formed in each side, into which wooden boxes are fitted. The pulley pin is formed with or fixed into the pulley, so as to turn in the wooden boxes. The top of the shell or case has a vertical hole opening at the bottom into an enlarged chamber, and the head of the bolt or hook by which the block is suspended fits loosely in this chamber, the shank passing out loosely through the hole.

TIRE-SETTER.—Francis Wime, Orland, Cal. No. 275,967. Dated April 17, 1883. The invention relates to an apparatus for removing tires from vehicle wheels and replacing them in their proper position; and it consists of a frame which may be secured to a bench or table or otherwise supported, and which carries an adjustable spindle and sleeve upon which the wheel is supported, so that its rims may be brought beneath a presser foot wheel and forced down by a lever or other power. The edge of the tire rests on a support so that the wheel felly may be forced out by the pressure. The device is specially useful in removing and replacing the tires of header wagon wheels and other heavy wheels. These tires are usually secured by bolts or rivets, which pass through holes transversely beneath the tire and have broad heads to prevent the tire coming off. These tires are usually knocked off and the felly often broken. By this apparatus the tires are forced off and on by gradual pressure, without hurting the wood work.

BEAUTIFUL skin and fair complexion, robust health and powers of endurance, follow the use of Brown's Iron Bitters.

FRUIT PLANTING.—One thousand acres of land have been planted, and a large part of it put under cultivation, at the new colony of Redlands, near San Bernardino, the present season. Raisin grapes are taking the lead, the red soil of which the tract is composed being especially adapted to their culture.

THE Mexican Government denies the report that Americans cannot acquire land in that country.

Our Agents

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. McGRAW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.

F. W. STRATTON—Calaveras and El Dorado counties.
I. M. LEHRY—Los Angeles, San Bernardino and San Diego counties.
A. C. KNOX—Oregon and Washington Ter.

F. A. HUNTINGTON'S**Centrifugal Roller Quartz Mill.**

After running one of these mills on the Whidden mine, in El Dorado County, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop stamp mill:

1. The cost of same capacity is not more than one-half that of Stamps.
2. Freight to mine one-fourth that of Stamps.
3. Cost of erection at mine one-tenth that of Stamps.
4. It runs with one-third the power per ton of ore crushers.
5. The wear is less than that of Stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine tenths of the gold in the mill (the balance can be saved on plates in the usual manner).
9. It is continually crushing, not like the Stamp, using power to suspend it in air ninety nine one-hundredths of the time, and the balance making a thundering noise and accomplishing comparatively small results. It is as far in advance of the Stamp Mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

Capacity and Durability Guaranteed.

Oscillating Stamp Mill.

It has no Stems, Cams, or Tappets, and adjusts itself to the wear of the Shoes and Dies.
For simplicity, economy, durability and effective working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power. Awarded First Premium and Medal at Mechanics' Fair, S. F., 1880.

Manufactured by
F. A. HUNTINGTON, FRASER & CHALMERS,
45 Fremont St., S. F., Cal. 115 Fulton St., Chicago, Ill.
Improved Patent Grinding and Amalgamating Pans, Concentrators and Gold Amalgamators; also, Steam Engines and Mining Machinery of all kinds. Send for circulars.

F. A. HUNTINGTON,
45 Fremont Street, San Francisco, Cal.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in a very short time. One machine will concentrate the tailings from a five-stamp battery.

Send for Circulars.

SHINGLE MACHINE.

For simplicity, durability and rapidity of action, these Machines have no equal, cutting from 3,000 to 4,000 per hour. They are now used by all the principal Millmen on the Pacific Coast.

Swedish Blast Furnace.

In some of the Swedish mines poor ores—four to five per cent of black copper—are worked and divided into two classes first. The smelting of the ores involves four operations, consisting of two calcinations or roastings, and two fusions, exclusive of the refining of the black copper produced in the blast furnaces in the two fusions. The ores are roasted or calcined in heaps or kilns, or any convenient way. The furnace is what interests us. The second stage consists in producing a regulus containing from twenty to thirty per cent of copper, obtained by treating the roasted ore with black copper slags, and occasionally, also, carbonate of lime in a blast furnace.

The furnace shown in the engraving is known as the ore furnace, which is provided with four, or, in more recently constructed furnaces, with three horizontal twyers, *a, a, a*, placed in the arch, *f*, of the back wall of the furnace. The shaft of the furnace is rectangular in section, the back wall being vertical, while the front wall, supported upon the tympanum, *b*, and an iron girder, rises vertically for a short distance, then inclines towards the back, and so narrows the section of the stack towards the top; the hearth projects beyond the line of the front wall, and the tap-hole is situated at one corner of the fore-hearth so formed. The hearth is lined with a mixture of clay and sand well rammed in, and beneath is a drain for the escape of moisture. These furnaces measure from twenty to twenty-four feet in height, and are about four feet in diameter at the level of the twyers.

Smelting in these furnaces is most frequently attended with the production of a ferri-ferrous mass or "bear," which collects in the bottom of the hearth; and resulting from the presence of incandescent carbon, together with the reducing atmosphere of carbonic oxide in the furnace, whereby a proportion of the oxide of iron, formed in the roasting of the iron pyrites contained in the ores, is reduced to the metallic state according to the reaction described under iron smelting; and these masses accumulate the more rapidly if the roasting be carried too far, and less slowly if a proportion of sulphur be left in the ore. Indications of the working of the furnace are afforded by the appearance of the furnace eye, at the end of the slag prolongation of the twyer, under which the furnace is always worked, for, if too much slag be added to the charge, the nose forms too rapidly, whilst the reverse is the case if an excess of fuel be added. The furnace being at work, the regulus and slag collect in the hearth, and at intervals about two thirds of the slag, which is essentially a ferrous silicate floating above the regulus, and will not contain more than .25 to .5 per cent of copper; is tapped out into sand beds and thrown away, while the remainder is returned to the ore furnace with succeeding charges. The furnace is only finally tapped when the hearth has become quite filled with regulus, which usually happens in from two to three days, when it will contain about five tons of metal, which is run out into sand beds, and when cold it is broken into pieces for roasting in the next (third) operation. The fuel employed is either coke or charcoal, latterly the former has come into more general use, and the practice of using hot instead of cold blast has been introduced.

RENTS were never so high at Chicago, the advance this season averaging over twenty per cent, and in some over fifty per cent.

Pacific Coast Mining Exposition.

We have before referred to the proposed Pacific Coast Mining Exposition to be held in this city during the month of August. Circulars have been sent to the Supervisors of each county in the State asking their co-operation in the matter of providing an exhibit from the respective counties. Other preparations are also being made.

The exhibits will be in two general classes, viz: donations to the State Museum, which

inches in diameter, excepting very rare or valuable minerals.

2. Wrap each specimen up carefully in paper; with a label inclosed, stating locality as exactly as possible—section, township, and range, and name of county—also the name of donor.

3. When two or more specimens are sent at the same time, observe Rule 2, and pack together tightly, so as to avoid any rubbing of the specimens.

4. When a number of specimens are sent in one box, in addition to the regular label (Rule 2,) have them numbered and a list with corresponding numbers made out and sent in the box.

5. Tack on the regular address card of the

SHAFT SINKING AND DRIFTING WITH MACHINE DRILLS.

will remain on permanent exhibition after the close of the exposition; and loan exhibits which will be returned to the owners at the close of the exposition. In order to make the exposition worthy of the State, the committee ask citizens to forward directly to the State Mining Bureau, or through their own county committee, any specimens which may represent any of the

State Mining Bureau, or address "State Mining Bureau, 212 Sutter street, San Francisco."

6. Use every precaution in sending fragile specimens; pack separately in a small box so that they do not damage from defective packing.

7. Before sending unusually bulky or weighty specimens, correspond with the Secretary of the committee concerning same.

8. Advise the State Mining Bureau of every

SWEDISH FURNACE FOR COPPER.

Plan of Swedish Furnace.

STARTING A TUNNEL.

resources of the State or are of interest otherwise.

It is desirable to exhibit specimens of ores occurring in the State, such as gold, silver, copper, lead, antimony, tin, nickel, quicksilver, iron, etc.; also clays suitable for brick, fire-clay, pottery, porcelain, etc. Useful and ornamental stones for building, paving and statuary, lime, plaster, etc.; cements, natural and artificial; mineral oils, crude and manufactured; soda and borax, crude or manufactured; nitrates, chromic iron, rocks and minerals of all kinds, salt, coal, fossils, woods, native and cultivated; fibrous plants, native and cultivated; paper material, native and cultivated; tanning material, native and cultivated; sands suitable for glass making, etc.; mineral soap, soapstone, Indian relics, and specimens of curious natural formations of any kind that may be interesting.

Specimens will be received from now on to August 1st. The committee have issued the following directions for exhibitors:

1. Specimens should be not less than two

shipment, stating when and how the shipment was made.

9. Send all small packages of twenty pounds or less, by Wells, Fargo & Co.'s Express and charges will be attended to at this office.

HON. JOSEPH WASSON, U. S. Consul at San Blas died there a short time since. Mr. Wasson was for many years a journalist and mining man in this State. It was entirely due to his efforts that the State Mining Bureau was founded.

FROM all accounts, El Dorado county is having a boom in quartz mining, as within the past year there have been a number of excellent developments, and many new mines have started up. The increase in the number of stamps is far greater than in any previous year. Grizzly Flat and Henry's Diggings are the scenes of the most active operations.

Machine Mining Drills.

The use of power drills is now absolutely necessary in all extensive mining operations, and, where a few years ago there was one of them in use there are now ten. In small mines people manage to get along the old fashioned way, but it is not from choice but rather from necessity. In operations of any magnitude, however, air compressors and machine drills are essential. The engravings shown on this page show, in a small space, the more common uses to which these drills are put.

The upper one of the engravings represents a shaft-sinking scene where the Ingersoll drills are arranged for vertical and angular boring in the shaft bottom, and drills, mounted on columns, are working in the drifts each way from the shaft. A bucket is being lowered with a new set of drills for the machines. The power to the drills is supplied from a common air pipe, and this power from the one compressor is sent to any part of the mine. The small engraving is intended to represent the starting of a tunnel into a mountain, where the men are getting ready to form a "face."

THE PROSPECT.—Under the above head the Walker Lake *Bulletin* editorially gives its birth-place the following send-off: Certainly no town in the State has a better outlook than has Hawthorne. The mines now developed in the immediate neighborhood give it a certainty of a large amount of business for years to come, while there are innumerable claims in all directions, which only need the expenditure of a little capital to make them wealth-producing properties. Not a day passes during which some new strike is not reported, and the season for active prospecting has scarcely begun. Of course all the discoveries now being made will not develop into paying mines; but where there are so many, no reasonable doubt can exist that some of them, possibly many, will rival in extent and value the pioneer in development, Mount Cory. Nearly all the rich districts are in a section of which Hawthorne is the natural base of supplies, and even now, while being simply prospected, they pay a fair tribute to the business men who have located here. In a few months the county buildings will be built, and all county business will be transacted here. This will also help materially the commercial aspect of the future, and will give a permanency which will prevent discouragement during the depressions incident to the ups and downs of mining excitements.

THE South Yuba River Tunnel Co., at Hoyt's crossing, have their tunnel in 700 feet, leaving about 300 feet to run, which will require from three to four months. Diamond drills are used in the work, which is being carried on now from both directions. This tunnel is fifteen feet wide, and nine feet high in the center. It extends the entire distance through hard granite. When finished it will enable the owners to work a long section of the river bed, which is believed to be very rich in gold, as the stream can be diverted from its natural channel into and through the tunnel.

THE Calaveras *Chronicle* says that there was a heavy execution sale made last Wednesday by Sheriff Thorn, of the property owned by the Calaveras Water and Mining Company and the New York and Calaveras County Mining Company. The property consisted of the hydraulic mines known as North and South Hill, near Jenny Lind, together with all the mining appliances, ditches and reservoirs. The property sold for \$25,000, and was bid in by Wm. P. Miller, who was the plaintiff in the action and who had recovered judgments amounting to \$40,000.

A YOUNG Cornishman named John Davis, recently found a "pocket" near Tuttle town, Tuolumne county, from which he has taken upwards of \$4000.

English Investments in the Pacific Coast Mines—No. 3.

[Prepared for the MINING AND SCIENTIFIC PRESS by H. DEGROOT.]

Other Unfortunate Utah Investments: The Flagstaff Venture and its Results.

Encouraged by the much good fortune that seemed in waiting for the Emma investors, the British public were led to embark their means in other of these far off, little known and ill-started Utah mines, the Flagstaff, also located in Little Cottonwood canyon, being the next property to pass into their hands, the sale having been effected in 1871. As in the case of the Emma purchase, the price paid for this mine was greatly in excess of its actual value, although a large body of rich ore had been developed in it prior to its transfer to the English company. The capital stock of this company was fixed at £300,000, all, as usual in that country, fully paid up.

When the new owners came into possession of the mine it was estimated to contain 30,000 tons of gray and yellow carbonate ores, three and a half tons of which made one ton of base bullion. During the year 1872, 10,500 tons of ore were extracted from the mine and reduced by the two smelters, producing 3,000 tons of bullion, the total value of \$750,000. The net earnings of the mine for the year amounted to over \$380,000, nearly all of which was disbursed to the shareholders in dividends. The metal turned out here during 1872 consisted of silver, \$390,000—average, \$130 per ton; gold, \$120,000—average, \$40 per ton, and lead, \$240,000—average, \$80 per ton, the ore treated carrying about forty-five per cent lead. The prosperous career so entered upon by this English company in 1872 was continued with but little variation until the summer of 1877, when, all of a sudden, came the discovery that the ore reserves in the mine were exhausted.

Such being the case, the smelters were shut down and, the local office being without funds, the entire labor force both at the mine and the reduction works was discharged. So careful had the directors of the company been to pay over the net earnings of the mine to the shareholders that when this crisis in their affairs occurred they were not only without funds, but were considerably in debt. Out of these debts and questions involving the title to a portion of the mine, grew law suits, which, dragging along for some time and entailing much expense, ended in the entire property being disposed of at sheriff's sale and passing into other hands.

Having, through this short sighted and improvident policy, suffered this really good mine to slip from their grasp, the directors, acting in concert with the shareholders, began to devise means for its recovery. A new company was formed, or rather, perhaps it should be said the old company was reorganized, and a syndicate formed, the members of which addressed themselves to the business in hand in such an active and determined way that the end proposed was finally effected, the company coming again into possession of the property in 1880.

Ample funds having been provided under the new arrangement, all claims against the estate were liquidated. The work of development was resumed and has since been carried on with results that promise soon to restore the Flagstaff to its former position in the front rank of Utah mines. Up till the time of its sale to the English company, the Flagstaff had made as good a record as any mine in the Territory. It was at that time in prime condition, with a good plant and a large body of high grade ore in sight, and, despite the excessive price paid for the property, had the finances of the concern been administered with ordinary skill and prudence, the investment would have proved remunerative and every way satisfactory. Finding themselves with a large stock of ore on hand at the start, the management attacked and used it up with all possible haste, neglecting meantime to search after new ore bodies and have them in readiness against a time of need. To this mistake chiefly, were the subsequent disasters that overtook the company due. The neglect to provide a reserve fund for repairing accidents to the mine or works or meeting other contingencies, as are inevitable in the life of every mine, was another blunder, such as no prudent and well-ordered company would have been guilty of.

"Next!"

Following the Flagstaff was the sale of the Sparrow Hawk group of mines, Camp Floyd district, purchased by another English company and, of course, at figures out of all proportion to the real value of the property. On the consummation of this sale in London, October, 1871, the purchasers proceeded to organize a company with a capital stock of £120,000—12,000 shares of the value of £10 each fully paid up. A first-class twenty stamp mill was in good time erected on the ground and the work of ore reduction commenced. After flourishing for a short time troubles began to develop themselves. The ore, at first free milling, became base and intractable to a degree that precluded its being successfully treated without roasting; it also deteriorated somewhat in value as depth was attained; the upshot of these troubles being a closing down of both the mines and the mill, which latter had been built at a very heavy cost. This company, on suspending

operations, was not, however, indebted to any one, nor was the property involved in litigation.

They were even fortunate enough in one year to dispose of their mill for about one third of its cost, the company having, in this particular, experienced something of the good luck that attended the Farmington Canal Co., of Connecticut, who every summer mowed the tow-path and sold the hay. For their mines, however, these trusting Englishmen never received a dollar, these having been at first closed down and afterwards practically abandoned. This company never paid any dividends, the product of the mill barely sufficing to meet current expenditures and pay cost of necessary improvements made. The investment was a total loss, and this not through any glaring mismanagement, but simply because a great deal too much was paid for the property in the first place, and, because their ores, suffering some deterioration, became, at the same time, too base for treatment by simple mill process.

That the company instead of coming to a dead halt should have put up furnaces, roasted their ores and gone ahead, is the opinion of many well informed persons; our British cousins illustrating in their action on this occasion a disposition frequently manifested in their dealings with American mines—taking hold too brash and letting go too soon. Seeing the worthlessness of many of the properties put off on these people they no doubt acted wisely, however, in thus speedily dropping the most of them as they did, on the principle that no incubation, however protracted, can bring anything out of a rotten egg.

The Immigration Association of California.

How the Fame of the State is Being Spread Abroad.

The leading factor in the immigration movement now in progress toward our State, is the Immigration Association of California, which has its headquarters at No. 10 California street. The Association has its spacious rooms well filled with valuable records of the available government lands and testimony concerning the resources and adaptations of the State. It is continually doing vigorous work in sending information to the thousands who are applying for it, and is thus extending its work into all parts of the Eastern States and in Europe. Not less than 250,000 copies of a description of California in pamphlet form has been distributed.

The Association has advertised the resources of the State and its advantages in over 500 newspapers and periodical publications; secular, agricultural, and religious, having a wide circulation in the States east of the Rocky mountains and in Europe, and has caused the publication of elaborate articles upon California in English and other languages. The addresses of 20,000 farmers have been procured, comprising names from nearly every county in the western, middle, eastern, southern, and New England States.

Of French pamphlets, 5,000 of the same character, with State maps, have been distributed through agents at Havre and Bordeaux, France, and by various means in the United States.

Of German descriptions of California, with maps, 15,000 have been distributed by this office and through agents in the United States and England, Switzerland, Sweden, Holland, Brussels, Bremen, Hamburg, Holstein, Baden, Gera, Leipzig, Dresden, Nennminster and Austria.

Besides these, a large quantity of other printed matter, descriptive of local sections of the State, or treating on special topics of interest to immigrants and intending settlers, has been widely circulated, and 8,000 letters, postal cards, and circular letters, including those in foreign languages, have been sent to various parts of the world.

There have been distributed, throughout the United States and other English-speaking countries, direct from the office, through immigrant agents, railroad and steamship offices, and otherwise, 60,000 publications descriptive of the State, with 40,000 State maps.

These measures have brought forth numerous inquiries, and a large, direct, and continuous correspondence. Information of the most varied character in reference to all conditions and all industries of the State has been asked from and furnished by the Association. Letters to the number of 10,000 asking for information have been received, representing every State east of the Rocky mountains and many foreign countries, viz., Germany, England, Switzerland, France, Italy, Sweden, Austria, Russia, Belgium, Hungary, Poland, British China, New Zealand, Hawaiian Islands, and Australia, besides a large number addressed to our agents in some of these countries. Letters have been received from as many as twenty-seven States in a single day, besides those from foreign countries.

The number of actual personal applicants for land who have registered at the office is over 2,000. These represented every State in the Union and many foreign countries. The Land Officer's report shows what disposition has been made of these people, by way of directing them to homes.

The Association has kept up a continuous agitation in favor of the bill now pending in Congress, to prevent the unlawful occupation of the public lands, by furnishing members of that

body and committees, with different written and printed statements in reference to it.

The Association has been placed on the mailing list of different departments at Washington, and many statistical and other reports have been received for its library.

Thirty-three State newspapers are kept on file in the reading-room for the benefit of immigrants and many specimen California products are set forth for examination.

Work of the Land Officer.

With the aid of one assistant for ten months, a list has been made of all the lands in the San Francisco, Stockton, Sacramento, Marysville, Shasta, Valisala and Los Angeles land districts, and in Lassen county of the Snsaville district, in California, belonging to the United States.

These lands have been indicated on township plats, which have been bound in books by counties, making fifty-four books and nearly 5,000 plats.

The United States Surveyor-General's field notes, so far as deemed necessary for immediate use, have been copied on the same plats, or are being copied, showing, in a general way, the topography, character of the soil, timber, water, and availability for farming or other purposes, of each township, and more particularly showing the character of the four sides of every section. Thus a general description of each six square miles is shown, and a particular one of each 160 acres.

Nine hundred township plats in the United States Surveyor-General's office have been copied, comprising eleven counties, which are bound in twenty substantial volumes, similar to books of like character in United States land offices. These plats show all the streams, Spanish grants, lands owned by private parties and by the United States Government, and give a brief general description of the land.

The work, in eleven different counties, has been concentrated in county maps, showing at a glance all the public lands and their general character, also the private and railroad lands and Spanish grants.

Much information has been procured through the 150 letters from actual residents in different sections of the State, all bearing upon the advantages or disadvantages of the Government lands for the settlement of immigrants, and which is kept in a book for public inspection.

Scraps of interest to immigrants have been clipped from State papers, treating of the resources, general and special advantages of the different sections, and of particular crops or interests of the State in general, which have been arranged in two scrap books, one of the counties, and the other a book of general information. In addition to these, 32 scrap books have been opened, one for each county, and 23 others upon special topics.

Personal examination has been made of certain localities in San Luis Obispo and Mendocino counties, where there was reason to believe good Government land was to be found. It is designed to rapidly extend this work.

Maps of ten different counties, two of the State, and one of the United States, have been donated by individuals, County Supervisors, and the Interior Department of the United States. With those made in the office, we have twenty-one county maps in all.

A vast amount of Government land in the State has been found suitable for farming, and immigrants may be invited to occupy them without limit. If this were not proven to be true, new comers would have to depend wholly upon buying land of private holders at higher prices, and immigration would be slower and development longer delayed. Other States having large quantities of free as well as cheap lands to sell on long time, with low rates of interest, would have greater immediate growth, as well as permanent advantages.

Although the work is not half done, the Association begins to feel that it has not been in vain, and are better prepared to tell immigrants the exact location and character of the Government lands than any other State has ever been. A summary of the estimates of the Association concerning the character of the lands is as follows:

Area of California.....98,500,000 acres.
Area of unencumbered Government land.....43,795,600 acres.
Area suitable for lumbering, mining and other pursuits.....16,295,000 acres.
Area suitable for some agricultural purpose.....21,500,000 acres.
Area of lakes, bays, navigable rivers and lands steep or rocky, or otherwise not productive.....6,000,000 acres.

Where the Land is

The Plat Books of the Association show public lands subject to entry as follows:

Counties.	Acres	Counties.	Acres
San Luis Obispo.....	450,000	Tehama.....	850,000
Monterey.....	600,000	Sierra.....	210,000
San Benito.....	250,000	Yuba.....	40,000
Santa Clara.....	150,000	Butte.....	155,000
Santa Cruz.....	40,000	Siskiyou.....	2,655,000
Napa.....	40,000	Siskiyou.....	455,000
Sonoma.....	165,000	Calaveras.....	65,000
Lake.....	450,000	Stanislaus.....	65,000
Mendocino.....	1,500,000	Merced.....	190,000
Shasta.....	1,500,000	Placer.....	735,000
Lassen.....	2,700,000	Nevada.....	255,000
Colusa.....	235,000	Amador.....	365,000
Yolo.....	655,000	El Dorado.....	5,900,000
Tuolumne.....	655,000	San Bernardino.....	320,000
Santa Barbara.....	150,000	Los Angeles.....	2,500,000
Ventura.....	150,000	San Diego.....	18,180,000
Kern.....	2,000,000	In other 17 counties.....	42,295,000
Tulare.....	2,000,000		
Total.....			1,500,000

The description of these and other public lands has been published in circular form, and is being daily distributed to all parts of the world in large numbers.

Settlements have been begun in Mendocino, Lake, Shasta, San Luis Obispo, and Monterey

counties. Between 1,500 and 2,000 people have procured directions from the Land Office of the Association, and been sent to these and other counties of the State. How many have actually located, they have no accurate means of determining, but as very few of those sent out return, and those who do, go again to other points, they conclude that a large portion of them have settled.

What is Done for the Home Seekers.

Applications for information by letter are all carefully attended to. When the printed matter of the Association meets the expressed wants of the applicant, this is sent. Whenever special information is needed individual letters are written. The mails bring communications from twenty to twenty-five different States and countries each day. On the arrival of immigrants at the offices of the Association, each man is asked concerning the kind of farming he desires to follow, and if he has a predilection for any particular part of the State. If he has these he is furnished with plats showing the Government land suited to his needs or in the locality he chooses, and he then sets out to examine the lands and make his selection. He is also given letters of introduction to men whom the Association knows and trusts in the different regions. Nowhere else is such definite work for the benefit of individual applicants done as by our California Association.

Eastern and Foreign Connections.

The Association now has an agent at Council Bluffs, Iowa, who is weekly organizing companies of immigrants, and sending them on with the information they need. The agent is D. N. Horn, and he seems to be pursuing his work with vigor.

The Association is now preparing to send Mr. Paul Ocker to Germany, to bring out thence a company of immigrants by the New Orleans route. Mr. Ocker has already brought in several parties from Colorado.

Work is also being done at the east by the agents of the railroad companies, and wherever an opportunity is found to put the information concerning the State in good hands, it is adopted. So far as our observation goes, the office in this city is managed with much zeal and skill, and reflects much credit upon the Secretary, Mr. Street.

The Association and Its Officers.

This Association is supported by and is under the control of the business men of San Francisco. It is organized for the purpose of furnishing free information concerning California, and to assist immigrants in finding employment and permanent homes in the State. All possible care will be taken to have the information given by the Association clear and reliable. The revenue of the Association is derived from voluntary subscriptions. The receipts are now about \$800 per month received from 125 subscribers.

The officers are as follows: Arthur R. Briggs, President; Wm. L. Merry, Vice-President; W. Steinhart, Treasurer; C. H. Street, Secretary and Land Officer.

Board of Directors—Jas. R. Kelly, Wm. L. Merry, C. W. Whitney, Wm. Blanding, W. N. Hawley, W. Steinhart, T. L. Barker, J. V. Webster, Arthur R. Briggs.

Executive Committee—Jas. R. Kelly, T. L. Barker, Wm. Blanding, J. V. Webster, Arthur R. Briggs.

Southern Nevada.

The Carson Tribune thinks it may, with truth, be said that Nevada is having her dark day, and such is invariably the case in mining districts, especially so where enormous amounts of precious metals have been extracted from mother earth. In the early days of river mining in Sierra county, and other districts of California, money was easily made and as quickly spent, miners made thousands of dollars by their sluices, and sunk it in running bed-rock tunnels, in the endeavor to strike gravel deposits, and hundreds, aye thousands, of the venturesome ones sank their all, and were away their lives in labor in the attempt. Camps were deserted as worked out, and but few remained to look for precious metal in quartz lodes, but those who did so were afterward rewarded by striking fortunes in finding quartz leads in a locality where it was supposed nothing but placer diggings prevailed. In those days, mining was a legitimate business, and continued so until the great Comstock was discovered, since which time it has become a thieving, rascally, stock-jobbing affair; the miners on the Comstock have been systematically robbed of their wages, and the proceeds of the mines have gone into the pockets of the few, and thus the hard times that now afflict the people of the State were brought about. The Carson & Colorado railroad has opened a way for miners to go forth, as of yore, and with their picks develop quartz, which they can get hauled to mills and have worked without being robbed of the proceeds; men of means stand ready to purchase pay ore from those who extract it, and so a new era has commenced in mining matters. To improve the times, men must do as in the early days of the Pacific coast, leave the old and used up Comstock, take their blankets on their backs and strike out into the new country opened out by the private means of the owners of the Carson & Colorado railroad, for in the southern part of the State there is a greater Comstock than Storey county ever held within her rocky hills.

MECHANICAL PROGRESS.

Sources of Injury to Boilers.

Leakage at the girth seams and around the tubes at externally fired, horizontal tubular boilers is one of the defects most often found, and one which is sure to become very serious in a short time if not attended to, for it induces corrosion in one of its most dangerous forms. There is nowhere to be found a better illustration of the truth of the old saying, "A stitch in time saves nine," than in this matter; and also no better illustration of the economy and value of proper care and management for steam boilers. Leakage at the seams of boilers may be induced by a variety of causes, of which we need here mention only two—bad workmanship and bad management. When the defect is due to bad workmanship the only help for it is, generally, to dress and recaulk the edges of the plates. Sometimes, though not often, it will be necessary to cut out the old rivets, insert new ones, and then dress and recaulk. This also is generally necessary when a boiler has been overheated through shortness of water or otherwise. Sometimes too much lap is given the plate, when it becomes impossible to properly caulk the seams. The writer has in mind now a certain rotary bleacher, whereon the plates lapped four inches beyond the rivets. The result may be imagined. Obviously the only remedy in such a case is to reduce the lap.

Leakage is often induced by feeding cold water into a boiler, and delivering it close to the hot plates over the fire. Severe local contraction is thus caused, which no material can resist, and leakage is sure to follow. The solid plates of the shell are very frequently fractured in this manner. Where the use of cold water is unavoidable, the boiler should always be provided with a circulating feed pipe as a means of economy and safety. In too many cases, however, the seams are shaken by the habit which prevails extensively of pulling the furnace doors wide open without closing the chimney damper. This is a very common way of checking the generation of steam when there is a lull in the demand for it from any cause, and cannot be too strongly condemned. The effect of a large body of air of some hundreds of degrees colder than the furnace and boiler, rushing along the under side of the shell, is sufficient to loosen the best joint that ever was made, and in many cases it has fractured the shell through the solid plate. The effect of this is even more marked with some types of internally fired boilers, such as the "drop-flue," for instance, than it is with the common return tubular boiler.

Another fruitful source of damage to boilers, and one which has ruined thousands, is the practice of blowing a boiler off and immediately refilling it with cold water while the brick-work is red hot. Nothing will tear a boiler to pieces quicker than this. Boilers have exploded with disastrous effects from this cause hours after the fire had been withdrawn. Probably most persons not familiar with the matter would be surprised to know the pertinacity with which cold water will cling to the lowest point of a boiler under these circumstances. Local contraction of such severity is thus induced that nothing can withstand its effects, and a few repetitions are generally sufficient to ruin any boiler.—*The Locomotive.*

A NEW STYLE LOCOMOTIVE.—Strong's express locomotive is a novelty in this country, and bids fair to spring into general use on every road where its merits are properly appreciated. The designer of the engine spent a long time in England and on the continent, taking note of all the good points in locomotives used abroad, and upon his return constructed an engine embodying the results of his studies. In the boiler of Mr. Strong's locomotive, the corner bars and side stays are done away with, the fire-box is designed to insure complete combustion of fuel by burning the gases and sparks, the driver coupling so arranged that the side rod is unnecessary, and there is also a better distribution of wearing surface on brasses or crank-pins than is the case in ordinarily constructed locomotives when the power for both wheels is transmitted through the forward pin. The valve motion is also improved, and the feed water heated by a portion of the exhaust. In short, the locomotive is so constructed as to be economical and fast as it is desirable, and always have a reserve of power for a heavy train, while at the same time it is simple, and not liable to derangement, and safe for those who run it, as well as those who ride behind it, and one that shall burn its coal in so perfect a manner as to do away with the cinders and smoke.—*North American.*

POWER OF BELTING.—Horse-power of a belt equals velocity in feet per minute, multiplied by the width—the sum divided by 1,000. One inch single belt, moving at 1,000 feet per minute=1 horse-power. Double belts about 700 feet per minute, per one inch width=1 horse-power. For double belts of great length, over large pulleys, allow about 500 feet per minute per one inch of width per horse-power. Power should be communicated through the lower running side of a belt, the upper side to carry the slack. Average breaking weight of a belt, 3-16x1 inch wide—leather, 530 pounds. Three-ply rubber, 600 pounds. The strength of a belt increases directly as its width. The co-efficient of safety for a lace belt is: Leather=1-16 breaking weight; rubber=½ breaking weight.

How to Select a File.

On purchasing a file bear in mind that there are several qualities—first, second, third and fourth. The first quality is the best, and represents about seventy-five per cent of a manufacturer's product. Firm names are always stamped on files before they are tempered, and if, after they are finished, any of them are found to be poorly cut, or badly tempered, the firm name is ground off and one of several fancy names, coined for all qualities below the first, is stamped on each file belonging to a certain quality. Thus, if a file-maker should select the word "Jumbo" for his second quality files, all too poor for the first quality and too good for the third have "Jumbo" stamped on them. First quality files only bear the name of the maker, while fourth quality generally bear no name at all, and are seldom seen.

When you have thought of all these things, ask the dealer for a first quality file, bearing the name of a well-known file-maker. Select the heaviest file in the box (if there is any difference in the weight of them), for a heavy file is generally truer than a light one of nominally the same size, and is better for re-cutting; a re-cut file, by the way, being just as good as a new one. Take the file to the light and hold it in a horizontal position, the point of it toward you. The teeth will now be pointed toward you, enabling you to detect easily any imperfections that a bad file is heir to. If the conformation of the teeth is irregular or uneven, or if the color of the file is not uniform, let it severely alone. A spotted or mottled file denotes unevenness of temper. If, on the other hand, the file presents a clean, white color, it denotes that the temper is even throughout; and if, besides this, it has regular and perfect teeth, and bears the maker's name, you may rest assured that it is an excellent file. The best files are tempered at a low heat. Files of certain sizes and numbers made since the first of last June are of uniform weight, the file manufacturers of the United States having agreed upon a standard of weights and sizes.—*Manufacturer & Builder.*

WHAT NEXT?—The possibilities of human invention are almost unlimited, and when, in the light of the improvements of the last half century we attempt to surmise what the next hundred years may bring forth, we are lost in the possibilities of what may be. When the web press was introduced, which enabled our large dailies to dispense with hand feeding, and by stereotyping their forms and putting their paper up in webs to roll out their editions at the rate of 20,000 folded copies per hour, it was thought that the printers' millennium was pretty near at hand; but in the *American Patent Office Gazette* for February 13, we find a patent issued to New York parties for a machine, whereby the papers are wrapped and addressed as they come from the press, and by an electrically connected switch, which is automatically operated by the passage of a metallic stencil hand, sorted according to their post office addresses. *Cotton, Wool and Iron*, mentioning this remarkable invention, thus soliloquizes: "The next move will probably be a pneumatic tube, so that the machine can spit the papers, all assorted, right into the post office. We have now half a dozen kinds of type-setting machines, and if some one will only get up a patent automatic, self-adjusting, double back-action, cast-iron editor, the only man we shall need to keep about a newspaper office will be a porter to sweep up and lock the door after the edition is off."

THE EFFECTS OF PUNCHING ON METALS.—As early as 1869, M. Tresca began to study the effects produced on metals by punching, and even prepared a formula by means of which it was possible to calculate the form of the piece punched out. At the meeting of the Paris Academy of Science, on March 26th, M. Tresca produced some prisms of metal that had been subjected to the operation of punching by powerful American machines, and, although the penetration of the metal had been effected under conditions differing from those contemplated in 1859, the correctness of the general formula was found to be borne out by practice. M. Tresca drew attention to the fact that the internal motion of the substance varied according as the face of the punch was plane or lenticular. There is also this curious fact, that, when the face of the punch is plane, it does not enter into actual contact with the metal, on account of a depression made therein by the advancing punch, and which continues to the end of each operation of punching.

COLD AND HOT-SHORT IRON.—A Sheffield, Eng., iron founder has made a series of tests with samples of iron plates, with the view to ascertaining the heat or temperature at which iron that is neither cold nor hot-short is liable to fail in bending and is unsafe for work. He observes that iron is very similar to steel in this respect, but that the fractures are different, for while steel, at a certain temperature, fractured nearly through the sample, on account of its homogeneous character, iron fractured to the depth of one or more of the layers constituting the plate. Iron plates being made from a pile of various bars, according to the weight, size and quality of the plate required, frequent laminations occur. The experiments seem to show that the temperature most dangerous to the metal—that at which it is most liable to fail in bending than if bent cold—is from 400 to 450 degrees.

SCIENTIFIC PROGRESS.

The Storage of Electricity.

A contemporary correctly says that the interest of all who follow the advances in the application of electricity to the arts, is centered at present in the so-called storage batteries or accumulators. The dynamo machine, driven by the steam or water power, has solved the problem of producing electricity in any desired quantity, and at reasonable cost as compared with the old cumbersome and inconvenient chemical battery; and the development and perfection of this machine has really given the great impulse to the cultivation of electrical science and its useful applications that characterize the present time.
